EDITORIAL

LIVER BIOPSY – IS STILL AN OPTION?

Why this question? Maybe, because many papers which have appeared in hepatological literature in recent times have assessed different modalities for the evaluation of liver diseases. Here we refer to diffuse illnesses starting with the "classical" liver biopsy and progressing to non-invasive tests, such as biological tests, where blood results are used together for evaluation, or elastographic methods such as ultrasound based techniques.

These present times can be confusing for many people as we are in a transitional period. There are still many physicians that believe that the liver biopsy is the only method that can give a correct answer concerning the severity of a hepatic disease. However, a cohort of researchers have found that biological tests or elastographic methods can replace the liver biopsy, offering the same accuracy.

Let's take a look at this controversy. Liver biopsy was the first method for evaluation in the hepatological field and for more than 50 years was the gold standard. The severity of a disease was diagnosed by this method and also the prognosis and decision of the treatment was decided. This was the standard of care in these times and possibly the patient was not always the first consideration! Criticism of this method was the invasivity, the pain for the patient and sometime complications with rare fatalities. However, is it not normal to have some fatalities when you are conducting an initial research, not just trying to cure? Secondly, we must examine the performance of a liver biopsy (or performance in the "intent to diagnose"): how often do we have a very correct morphologic diagnosis in which we can trust? For a long time, this was not a real preoccupation of the physician, but when the competition of non-invasive methods appeared, the performance began to count. And here the statistical results are not very good. From the past we know that a liver biopsy can miss liver cirrhosis in approx. 20% of cases. More recently, in large cohort of patients, we found that an optimal morphological fragment is obtained in percutaneous liver biopsy in only approx. 40% of cases. Other methods of histologic evaluation (tranjugular liver biopsy) offered less hepatic tissue while additional factors such as interobserver variability between pathologists are well known. Some pathologists demonstrated that short liver specimens can underestimate the severity of the lesions, finally resulting in an incorrect histological appreciation. As a result of this and on account of the invasivity of the liver biopsy, researchers started to search for non-invasive modalities for liver evaluation, in patients with diffuse liver diseases.

Advantages: first for patient! No pain, no stress before this evaluation, repetitivity, not very high cost! The development of these methods was made first in Europe and France was the leader in this field. They developed biological tests, well known, like FibroTest-ActiTest (for activity and fibrosis evaluation) and later FibroMax (activity, fibrosis, steatosis, nonalcoholic and alcoholic steatohepatitis evaluation). In the field of ultrasound based elastography, FibroScan (Transient Elastography) was developed in France too. Many publications concerning the non-invasive evaluation of liver in comparison with liver

biopsy came from France (Poynard, Castera and others). From France came the first recommendation in the guidelines for the use of non-invasive modalities for liver evaluation as an alternative to liver biopsy. Later, the EASL (European Association for the Study of the Liver) Guideline proposed non-invasive modalities like an alternative to liver biopsy. During time, non-invasive modalities for liver evaluation were spread in other European countries (but, not only European). Others biological test were developed (like ELF, Hepascore, Lok, others) and other ultrasound based elastographic methods appeared and started to be evaluated (in comparison with liver biopsy and in the last time with Transient Elastography), like ARFI (Acoustic Radiation Force Impulse Elastography) or 2D-SWE (2D-Shear Wave Elastography, SuperSonic Imagine).

These non-invasive modalities for liver evaluation have spread everywhere in the world, from Japan, China and Korea to Canada and Brazil. Increasing number of patients are evaluated with these methods now, decreasing in the real world, the number of liver biopsies. Only in the USA there is still a delay for this introduction, maybe in connection with the severity of FDA regulations for the approval of such methods.

In this moment, many meta-analyses or large cohorts of patients have demonstrated very good results of these non-invasive methods for the evaluation of fibrosis (elastographic methods) or inflammation, steatosis and fibrosis (in biological tests such as FibroMax). These methods are good for the "intention to diagnose" a case, the failure rate being quite low and can be repeated as often as is necessary while being excellent for establishing the diagnosis of moderate or severe fibrosis (accuracy more then 85-90%). On the other hand, in some diseases, such as C chronic hepatitis, we have now very potent drugs, than can cure the vast majority of patients, irrespective of the degree of fibrosis. If we consider prioritising these patients, non-invasive methods are quite good.

Therefore, in the future, everywhere we shall see a decreasing number of liver biopsies (including in more conservative countries such as the USA). Probably, in a percentage of patients, the liver biopsy is still necessary (maybe in autoimmune hepatitis, colestatic diseases, B chronic hepatitis or others), or maybe for some academic studies.

For focal liver lesions (which is not the topic of our discussion), probably we shall see an increasing need for biopsy (echoguided), regarding the molecular medicine perspective or personalized treatment for every patient.

Finally to answer the question in the title: liver biopsy - is it still an option? Yes, is a good option, but in many cases it can be now replaced by non-invasive modalities of liver evaluation. Biological tests or elastographic methods or a combination of these two modalities (this combination can increase confidence) will replace many liver biopsies. The comfort and the safety for patients, their reasonable price and the excellent accuracy of these methods are the main arguments in the future for this new direction of evolution, from an invasive procedure (liver biopsy) to the non-invasive modalities of evaluation.

IN MEMORIAM

PROFESSOR GEORGETA DATCU, M.D., Ph.D.

(27 August 1939-10 August 2015)

The academic community of "Grigore T. Popa" University of Medicine and Pharmacy Iasi expressed by the voice of 1962 promotion its deep regret for unexpected loss of our distinguee colleague Professor Doctor Georgeta Datcu, teacher and head of the Ist Medical Clinic for more than four decades.

Originating in Bacau in a family of intellectuals, his father dr. Demostene Teja being a renowned radiologist and her mother being pharmacist, she naturally oriented toward medical career. High school graduating with honors she benefited a merit bachelor being admitted without examination and between 1956-1962 pursued the General Medical faculty courses distinguishing herself for intellectual qualities and passion of perfection in medical profession. As colleague and chief of our group she proved modesty and diplomacy, never wanting social roles, her politics being only school performance.

Due to its endowment but also to the great generation of masters we have benefited: I Iancu, I. Nițulescu, Gh. Chipail, I Enescu, Vl. Butureanu, Maria and O. Franke, Th. Economu i.e., she graduated with one of the highest accolades.

She became by competition apprentice (1960) and *house officer* (1962) carrying out her training in prestigious clinics mainly in internal medicine services.

In 1962 she sustained the licence thesis intitled *"Pseudartrosis of the rachisyntesis graft in Pott's disease in children"* conducted in Pediatric Surgery Clinic and appreciated with maximum qualifier.

In the Ist Medical Clinic she was spotted and guided by Professor Constantin Negoiță, known for the rigor of its staff selection who was her mentor and role model for entire career, dr. Georgeta Teja being the first in a series of valuable graduates, four of which becoming later heads of clinics. Therefore in 1965 she became jr assistant of this clinic where will activate for 44 years being successively promoted assistant (1968), lecturer (1983), associate professor (1990) and professor (1994). She became also registrar (1968) and consultant in internal medicine (1978) and cardiology (1983).

She led the clinic for 15 years until her retirement with professionalism, strictness and balance maintaining its excellence and reputation.

As practician outside her encyclopedic knowledge and holistic approach of the suffering, Professor Datcu had particular clinical feel destined only to "true doctors" always surprising by the finesse and accuracy of diagnosis and optimal therapeutic solution

Although her priority was competence in cardiology, like her illustrious predecessors Professors Bacaloglu, Niculescu, Tudoranu and Negoiță, Professor Datcu

demonstrated broad knowledge in other specialties of internal medicine.

She gave equal importance to teaching activity through clinical internships and demonstrations filled of attainments, dedication and patience stored in the memory of students but also of young colleagues, residents or physicians in training, all of them decisive benefiting in their education and perfection.

Her lectures have excelled by sober style without pedantry, logic and systematized, oriented to practice, all dressed in an elegant, worship language, always appropriate to the audience. Like her mentor, Professor Datcu had an impressing scientific activity not by the number but by the value of its works. Most of publications realized together with Professor Negoiță and collaborators from the clinic include clinical trials or casuistry published in specialty literature. As a tragic coincidence our last common work treating cardiothyreosis was printed quite in her dying day.

In 1984 she sustained her doctoral thesis having as theme the *"Study of capacitant vessels in systemic arterial hypertension"* headed by Professor Negoiță completing an original research spread over several years enjoying unanimous appreciations. In 1996 Professor Datcu became Ph.D. superviser in internal medicine and cardiology directing with her proverbial competence and exigency a number of theses.

Its main medical writings still remain chapters included in the treaty of Medical Clinic under the editorship of Professor Negoiță in 1995 (bronchiectasis, bronchial asthma, bronchopulmonary carcinoma) and those under editorship of her colleague and husband Professor Mihai Dan Datcu *"Clinical confrontations - commented cases"* 2003 and *"Controversies and diagnostic errors in cardiology"* 2009, all of great use and practical interest for students, residents but also specialized doctors.

She also participated actively and consistently with papers, reports or in quality of chairman at numerous scientific meetings with topics of internal medicine and cardiology, either autochthonous - some organized in Iasi – either abroad, established itself as one of the most prominent contemporary personalities of specialty Colleague and friend for almost sixty years I could appreciate the intelligence and culture not only professional of Professor Georgeta Datcu, her great character full of frankness, honesty, loyalty and altruism, all wrapped in a mantle of humor and Moldavian kindness.

Her disappearance - the first female professor of internal medicine in our country - is a heavy loss both for the Romanian medical world and for collaborators, colleagues and its friends.

God rest her soul….

Dr. Mihai Radu Diaconescu,
Professor of Surgery

CELL-FREE FETAL NUCLEIC ACIDS (cffNA) – NEW NON-INVASIVE PRENATAL DIAGNOSIS

Prenatal screening and diagnosis are routinely offered in antenatal care and are considered to be important in allowing women to make informed choices about the continuation of pregnancies affected by genetic conditions. Diagnostic testing currently requires removal of a sample of fetal cells directly from the uterus for genetic analysis, using either chorionic villus sampling between 11 and 14 weeks gestation or amniocentesis after 15 weeks. However, these invasive procedures carry a risk of miscarriage of around 1% (Mujezinovic and Alfirevic, 2007).

Cell-free fetal nucleic acids (cffNA) can be detected in the maternal circulation during pregnancy, potentially offering an excellent method for early non-invasive prenatal diagnosis (NIPD) of the genetic status of a fetus. Using molecular techniques, fetal DNA and RNA can be detected from 5 weeks gestation and are rapidly cleared from the circulation following birth.

Intact fetal cells circulating in maternal blood present an attractive target for NIPD, particularly for the diagnosis of fetal sex and chromosomal abnormalities by simple karyotyping. Although the existence of fetal cells in maternal blood has been known for more than a century, isolation of intact fetal nucleated red blood cells for the purpose of prenatal diagnosis was not achieved until 1990 (Bianchi et al., 1990). Since then, the isolation and detection of fetal cells from maternal blood has been extensively investigated and various methods of fetal cell enrichment developed. However, results to date have been disappointing, due to the scarcity of intact fetal cells in the maternal circulation (around one cell per ml of maternal blood), low efficiency of enrichment and difficulties with chromosomal analysis associated with abnormally dense nuclei in some cells (Babochkina et al., 2005). Although certain fetal cells (specifically nucleated red blood cells) have a relatively short lifespan in maternal blood (Lurie and Mamet, 2000), other fetal cell types can persist in the maternal circulation for decades following pregnancy (Bianchi et al., 1996), potentially causing false-positive results in subsequent pregnancies. The majority of recent research has focused on cell-free fetal DNA (cffDNA) in the maternal blood, of which there is significantly more present (by a factor of almost 1000).

Fetal DNA originates from apoptotic placenta cells (trophoblasts) derived from the embryo and comprises around 3 –6% of the total cell-free DNA in maternal circulation during early and late pregnancy, respectively (Lo et al., 1998b) (the other 94 – 97% being maternal cell-free DNA). Unlike cellular DNA, circulating cffDNA consists predominantly of short DNA fragments rather than whole chromosomes, of which 80% are, 193 base-pairs in length (Chan et al., 2004). Fetal DNA can be detected from the 4th week of gestation (Illanes et al., 2007), though only reliably from 7 weeks, and the concentration increases with gestational age-from the equivalent of 16 fetal genomes per milliliter of maternal blood in

the first trimester to 80 in the third trimester (Birch et al., 2005)-with a sharp peak during the last 8 weeks of pregnancy (Birch et al., 2005). In contrast to fetal cells, cffDNA is rapidly cleared from the maternal circulation. cffDNA may be detectable for several days following termination of a pregnancy (Wataganara et al., 2004a).

Additionally, cell-free fetal mRNA (cffRNA) has also been detected in the maternal circulation in 2000 (Poon et al., 2000), derived from genes that are uniquely actively expressed in the placenta. Although the majority of work to date has focused on cffDNA, both types of cffNA, i.e. DNA and RNA, could potentially be used for the NIPD of specific genetic characteristics of the fetus.

There are a number of general problems associated with detecting cffDNA in the maternal circulation: (1) the concentration of all cell-free DNA in blood is relatively low; (2) the total amount of cell-free DNA varies between individuals; (3) cffDNA molecules are outnumbered 20:1 by maternal cell-free DNA molecules; (4) the fetus inherits half its genome from the mother.

The most common technique currently used for detection and identification of specific cffDNA sequences is polymerase chain reaction (PCR). A number of different types of PCR have been explored, of which the most popular is real-time quantitative PCR, as it combines high sensitivity with a closed detection system, thereby minimizing the risk of contamination. Higher precision of measurement may be possible through the application of digital PCR, which allows the exact number of original template DNA molecules to be counted (Fan and Quake, 2007; Lo et al., 2007a). Another sensitive technique that has recently been applied to the identification of cffDNA is mass spectrometry (Ding et al., 2004), in which the precise mass of each DNA fragment is analysed to determine the genetic sequence, and hence detect fetal-specific alleles that differ from the maternal sequence by as little as a single base.

Owing to the difficulties with isolating cffDNA from the maternal circulation, its diagnostic potential at present is limited to known differences between fetal and maternal genomes. It is important to emphasize that complete fetal genotyping is not conceivable using cffDNA in the maternal circulation and that the genetic information derived from cffDNA is entirely restricted to the specific DNA sequence (or chromosome) detected. However, given modern high-throughput technologies, such as DNA microarrays (Ge et al., 2006), thousands of different sequences could potentially be detected simultaneously if required for multiple diagnoses. There are a number of quite discrete clinical applications of cffNA analysis in prenatal screening and/or diagnosis, based on distinct and detectable differences between fetal and maternal genomes:

(1) sex determination - by detecting cffDNA sequences on the Y chromosome. NIPD of sex using cffDNA is applicable to any sex-linked disease, to date it has been published within the context of haemophilia, Duchenne muscular dystrophy, X-linked mental retardation, adrenoleukodystrophy, Alport's syndrome, X-linked severe immunodeficiency, retinitis pigmentosa, X-linked hydrocephalus, anhidrotic ectodermal dysplasia, Hunter's syndrome, Menke's syndrome and Lesch–Nyhan syndrome (Costa et al., 2002), as well as some endocrine disorders including congenital adrenal hyperplasia (Chitty et al., 2007).

(2) single gene disorders (autosomal

dominant diseases: Huntington's disease, Acondroplasia, Myotonic dystrophy) or autosomal recessive diseases (Cystic fibrosis, Hemoglobinopathy, Congenital adrenal hyperplasia (21-hydroxylase deficiency) - by detecting a paternally inherited allele in cffDNA.

(3) pregnancy-related disorders - by detecting either the presence of a working copy of the Rhesus gene or an elevation in the absolute concentration of cffDNA. Numerous studies have shown conclusively that the level of cffDNA (usually measuring Y chromosome DNA of male pregnancies) is elevated by 2 – 3-fold before the onset of preeclampsia and 2 – 14-fold during preeclampsia (Hahn et al., 2005). A number of other pregnancy-related disorders have been linked to an elevated concentration of cffDNA: preterm labor, *hyperemesis gravidarum*, invasive placentation, intrauterine growth restriction, feto-maternal hemorrhage and polyhydramnios.

(4) aneuploidy - by detecting an abnormal concentration of a particular chromosome, potentially using cffRNA specific to the fetus and chromosome of interest. For trisomy 21 and other common aneuploidies, we found that cfDNA testing had a higher sensitivity and specificity in a general prenatal screening population. The false positive rate of cfDNA testing was nearly 100 times lower than that of standard screening.

However, maternal serum and nuchal translucency screening can identify risk for a broad array of abnormalities that are not detectable on cfDNA testing.

Although these data support the use of cfDNA testing in women regardless of age or risk status, further cost utility studies are warranted. As emphasized by professional societies, the use of cfDNA testing and other genetic tests requires an explanation of the limitations and benefits of prenatal test choices to the patient.

THERAGNOSTICS - A SILENT REVOLUTION

Medicine has evolved over time based on two distinct components: new concepts on how to integrate and interpret the various data available and the continuous technological evolutions that provided more precise data concerning patient's status. While this second part is constantly viewed and publicized in the media as driving effectiveness of health care this is in fact not entirely the case and major changes in the modalities to view the disease concept have driven major changes.

Medicine started as an art of healing based on philosophical consideration about health status and the possible modalities to reverse disease status to health. Hippocratic medicine has introduced the direct and systematic observation of clinical signs and the theory of the equilibrium of humors and marked a rupture with the previous concepts of the divine nature of disease. Hippocrates had a deterministic view of the health and disease status and that both could be influenced by concrete actions of man. The following 2,000 years were marked by a better understanding of basic principles of anatomy and physiology in parallel of the development of the techniques of macroscopically and microscopically examinations but without major developments in terms of therapeutic options. The next step in our understanding of illness was the development of the anatomo-clinical method proposed by Giovanni Morgagni and developed by Xavier Bichat, René Laennec and Jean-Martin Charcot. For them every disease and clinical sign had an anatomo-pathological correspondent and therefore it was sufficient to carefully know these correlations in order to proper diagnose a disease. This approach led to the identification of most of the major nosologic groups known today. In parallel, the introduction of Claude Bernard principles of scientific experimentation resulted in major understanding of the disease process and massive advancement in term of available efficient therapeutic interventions. However this approach resulted in an archetypal understanding of disease and each patient was fitted in a global model of the pathological process without clear possibilities to explain differences in presentation, evolution and response to treatment between patients. Progressively, the understanding of individual variability due to a better understanding of human genetics and its interactions with environmental variables based on the advances in molecular biology and epidemiology set the foundation for *personalized medicine*, the next evolutive step in medical science.

Until then a relatively homogenous group of patients as defined by various clinical, biochemical and pathological features will receive the "standard" best treatment available and afterwards interventions were adapted based on response to treatment and toxic effects of therapy. This result in three groups of patients: those who benefit from therapy and improve / cure patients who do not benefit from therapy and patients with toxic effects from therapy with some possibilities of overlap between these groups. Using this approach the critical issue was to correctly name the disease process without

any possibility to predict in advance how our patient will respond, this being usually inferred from a post hoc analysis. Eventually, treatment strategy was modulated based on heuristics resulting from previous experience of the clinician.

Advances in the understanding of genetic background of disease and patients enable us now to predict to some extent which disease will respond to a particular treatment and which patients will have toxic effects from therapy. Thus major progresses were possible concerning treatment: we know expect to be able to predict the effects of therapy both in term of efficacy and toxicity thus maximizing benefit of therapy.

Still, such an approach is not without difficulties. First we need to have a good understanding of the disease process at the molecular level. This represents an important effort which should be done for every disease process we know or that is newly identified. The actual experimental approach is not sufficient for this since we need to cover most if not all disease subtypes. For this to be successful, we first need to obtain biological samples at every level (biopsies, blood and other bodily fluids) store them in large biobanks and to have access to a complete clinical and therapeutic profile of individual patients. The development of robust statistical methods for analysis of these *"Big Data"* collections is also a challenge since classical statistical analyses are not applicable.

Second we need to completely change our way to develop drugs. Instead of testing *"blindly"* a large number of drug in preclinical or animal models and then in clinical trials we need to create (in parallel to drug development) a companion diagnostic test than is sufficiently predictive for drug efficacy. This necessity is not only imposed by the need to maximize drug benefit but mainly for diminishing toxicity and to limit the cost of treatment. Indeed the costs of drug development are rising fast and consequently innovative drugs have very high prices despite of a limited increase of the production costs. Thus it is no more possible to administer drugs to all patients and then evaluate their efficacy because such an approach is not sustainable from the payer's perspective.

This whole new domain called *theragnostics* is rapidly imposing itself as the standard approach to disease and today most developments of drugs follow this path. Despite being promising we still need global analyses both from clinical trials and from day to day practice that prove that such an approach will both improve treatment success and keep costs at a tolerable level.

Professor Bogdan Dragoş Grigoriu, M.D., Ph.D.

PAIN MANAGEMENT: STRATEGIC GUIDELINES

„Pain does represent a major health problem all over the world. Although acute pain is more often a symptom of an injury or disease, chronic and recurrent pain is a specific health problem, being a disease itself" (1, 2).

As a counselor of the European Federation of the local chapters of the International Association for the Study of Pain (IASP) I have expressed in 2001 my support for the statement „Chronic Pain a Major Healthcare Problem, a Disease on its Own Right", launched in European Parliament, in Brussels. The text of the Statement (from which I quoted in the introduction) was conceived by the professors David Niv and Marshall Devor and was previously discussed and approved by the Council of the European chapters of IASP, only after each branch has provided the relevant informations concerning the different aspects of the study and management of pain in the respective membership countries.

If symptomatic simple, acute pain is easier to manage, the chronic pain, by its duration and intensity is responsible for the drastically limitation of life quality, affecting work, social and private life. For these reasons, pain should be considered among the top priorities of the healthcare system.

The above mentioned document shows that the approach of the adequate prevention and therapy of the chronic pain should be ruled from different perspectives, which must include: modern diagnostic techniques availability, accurate information of the patients, the right to benefit of the most modern invasive and non-invasive therapy methods, as well as a satisfactory monitoring. Like this were drawn main strategic guidelines in the management of the chronic pain.

In the following years, in some countries were conducted efforts in order to optimize pain management through training specialists, facilitating the availability of powerful analgesics or some legislation initiatives. However, notable differences did perpetuate, between southern European and northern European countries, and especially between eastern and western European countries.

Several countries did recognize chronic pain as a disease itself; unfortunately this is not the case in our country.

2001 European initiative had a positive impact all over the world, also generated a more wide and generous approach of the problem by IASP, which supported the idea that pain management is part of the human fundamental rights.

This gave birth to another initiative, which was brought alive on the occasion of XIIIth World Pain Congress in 2010, under the name of „Declaration of Montreal". The document is stating the will of more than 260 pain specialists from 80 countries; after stressing the inadequate access of patients to different therapeutical methods used in the treatment of acute and chronic pain, the lack of specialists, the barriers in what concerns the availability of opiate analgesics, was proposing a set of measures destined to implement national strategies in the field of pain (Romanian Algesiology Association was among first organizations which expressed their support for the initiative) (4).

An outcome of the Declaration of Montreal was the European Parliament Pain Symposium organized by the European chapters of IASP, in Brussels in May 2011, entitled „Societal Impact of Pain". On the occasion professor Giustinno Varasi (ex-president of the European Federation of IASP) was restating that pain should be considered a major health problem by the governments of all European countries, since patients had the right to benefit of the most adequate invasive and non-invasive therapeutic methods and a satisfactory monitoring (1, 6).

European statistics shows that about 25% of the European population has suffered articular, muscular or vertebral column pain, with duration of more than three months. This suffering is resulting in enormous social costs, which should determine political and decisional factors to adopt adequate strategies and to provide resources able to solve this difficult problem.

In our country were achieved some initiatives, such as the development of palliative care centers, in some locations; unfortunately these initiatives are drastically limited by the chronic underfinanced medical system.

2011 European Document is underlying the differences between its members, in what concerns the opportunity to take good care of their health. Significant statistical data are thus demonstrating that populations with low educational level are more often affected by pain suffering than those with a consistent educational level, especially because higher social and economic status is providing a better access to healthcare means. On the other hand, the growth of the average life duration is leading to an increase of the risk for development of chronic pain, with approximately 30-40 % in the following 20 years. Chronic pain is often associating anxiety and depression, thus being reflected in mental health of the individuals, which is further increasing the costs of the chronic pain.

We must understand that chronic pain is not only a disease itself, but it is generating problems which are involving the health system (diagnosis, hospitalization, medical prescriptions), ensuring companies (overspending), as well as the community (work incapacity, inefficiency, disabilities, low life quality).

At a review of the recent statistical data (2009-2013) regarding the powerful analgesics consumption in Europe, considered as main marker of the therapy of severe pain, we can notice embarrassing discrepancies (as we have been signaling previously) between the consumption level in the western and eastern European countries. From the table made by the author, form data provided by *Pain & Policy* studies Group and published in *Pain Europe* review, in which is presented the total morphine equivalent (in mg/capita), we see values which are confirming the above observation (3, 5).

Country	**Total Morphine Equivalence mg/capita**
Germany	395
Norway	274,12
Great Britain	253
France	210
European mean[x]	135
Bulgaria	68,8
Ukraine[x]	11,9
Moldavia[x]	8,75
Russia[x]	2,04

[x] In some countries the reported data are incomplete

From the table, data regarding Romania are missing, since they were not reported by our country to the international charged authority, and the efforts of the author to

obtain those data from the Health Department or from National Health Insurances House lead to inconclusive results.

Otherwise, from the discussions with colleagues, specialists in the field from eastern and southern European countries emerged the idea of a persistent „catastrophic approach", regarding morphine and derivatives prescription. Even in the cases with a more permissive legislation (Romanian Law No.339/2005), ***physicians do fear to prescribe, pharmacists to stock and patients to accept a therapy with morphine or other potent opiate substances.***

On the occasion of „World Medicine Park", which took place at the beginning of may 2014 in Minorca island (Spain), was stressed the importance of improvement of patients perceptions in what concerns the opiate analgesics, since it was estimated that each year, more than 5.5 million patients with terminal cancer do not receive the adequate therapy for their suffering (7).

Taking into consideration all the above elements and trying to adapt them to specific conditions of our country, we can draw the following main strategically guidelines:

- ✓ the need to organize medical centers and clinics exclusively destined for the management of the chronic pain as a disease itself;
- ✓ placement of the diagnosis, and when is possible of the therapy of the chronic pain at the primary level of the medical care, which is that of family medicine physicians;
- ✓ the need for continuous education on the modern means of pain diagnosis and therapy, in view of preventing the evolution of such cases toward the estate of „chronic patients";
- ✓ actual and potential patients should be thoroughly informed to know how to avoid those conditions which could generate or enhance their pain problem at workplace;
- ✓ we should identify significant financial resources, (not from the Health Department, only), for continuous translational researches in the field of the pain therapy and for the discovery of less expensive and more efficient new analgesics.

INFECTIOUS COMPLICATIONS IN PATIENTS WITH LIVER CIRRHOSIS

Sînziana Preda, Anca Trifan, Irina Gîrleanu, C. Stanciu, Camelia Cojocariu
University of Medicine and Pharmacy "Grigore T. Popa"- Iaşi
Faculty of Medicine
Discipline of Gastroenterology
Institute of Gastroenterology and Hepatology

INFECTIOUS COMPLICATIONS IN PATIENTS WITH LIVER CIRRHOSIS (Abstract): Liver cirrhosis is the end stage of any chronic liver disease. Complications occurring in patients with liver cirrhosis may be specific to this pathology and to gastroenterology (upper gastrointestinal bleeding, hepatic encephalopathy) or may interfere with other specialties (hepatorenal syndrome, spontaneous bacterial peritonitis, and other localized infectious complications). Over the past few decades, major efforts have been made to increase survival in patients with cirrhosis, but unfortunately, few therapeutic methods have been proven effective. Bacterial infections are frequent and serious complications of liver cirrhosis, resulting in high morbidity and mortality, especially in hospitalized patients, despite significant progress in health care for those with advanced liver disease. **Keywords:** LIVER CIRRHOSIS, INFECTIOUS COMPLICATIONS, BACTERIAL, MORTALITY.

EPIDEMIOLOGY

The estimated incidence of infectious complications in hospitalized patients without liver diseases is 5-7%, significantly lower than in cirrhotic patients (30-40%) (1).

Intrahospital mortality in cirrhotics with infectious complications is approximately 15%, significantly higher than in those without infectious pathology, while mortality from infectious complications is 20 times higher in patients with cirrhosis than in general population (2).

The most frequent infectious complications in cirrhotics are spontaneous bacterial peritonitis (25%), infections of the urinary tract (20%), pneumonia (15%), bacteremia (usually after therapeutic procedures - 12%), and cellulitis (1.2%) (1, 3).

Diagnosis and initiation of therapy are often delayed in infectious complications of cirrhosis due to negative bacteriology findings (culture and antibiogram). Blood cultures and cultures from ascitic fluid are positive in only 50-70% of cases (1).

Bacteria responsible for infectious complications are mostly Gram negative bacilli, especially *Escherichia coli*, accounting for almost 60% of infectious complications; Gram positive bacilli account for 30-35% of infectious complications, while bacterial association is confirmed in 5-10% of cases. Together with *Escherichia coli*, *Staphylococcus aureus*, *Enterococcus faecali* and *Streptococcus pneumoniae* are the bacterial agents that cause infectious complications in patients

with liver cirrhosis.

Among infections occurring as complications during hospital stay, over 60% are caused by Gram positive cocci (4).

PATHOGENESIS

Patients with liver cirrhosis are exposed to infectious complications, but the mechanisms of an increased susceptibility to infection in these patients have not been fully established yet. Several mechanisms and favoring factors are suggested: qualitative dysfunctions of the reticuloendothelial system, increased intestinal permeability, presence of systemic shunts, systemic inflammatory response syndrome (5).

Immunodeficiency

Liver cirrhosis is characterized by a dysimmunitary status of multifactorial etiology, in which occur: decrease in the bactericidal activity of phagocytes, lower opsonic activity, low complement and protein C levels, alteration of the reticuloendothelial system, the main defensive system against hematogenously acquired infections (alteration of Kupffer liver cells activity and the existence of porto-systemic shunts result in deficient purge of systemic bacteria and endotoxins) (6).

Bacterial translocation is an important factor in the pathogenesis of infectious complications in cirrhotic patients; this mechanism is one of the key elements in the pathogenesis of spontaneous bacterial peritonitis and spontaneous bacteremia in liver cirrhosis. In conditions of sympathetic hyperactivity, in cirrhosis the reduction of intestinal motility favors stasis and bacterial overgrowth (7). In its turn, portal hypertension causes edema of submucosa and a change in intestinal permeability, thus favoring the translocation process (8).

Systemic inflammatory response syndrome (SIRS)

Sepsis is the systemic inflammatory response syndrome to infection. Other causes, such as acute pancreatitis, burns, and traumatisms, may also cause the same *systemic inflammatory response syndrome (SIRS),* but without infection as an etiological agent. The exact definitions of these syndromes cannot always be applied as such in liver cirrhosis, as patients may have leucopenia due to hypersplenism, increased basal heart rate (HR) due to hyperdynamic syndrome, hyperventilation caused by encephalopathy, or absence of fever syndrome.

Patients with liver cirrhosis present numerous factors that favor the occurrence of infectious complications, mostly with progression to septic shock, multiple organ failure (MSOF) and, eventually, death (9). One of the pathogenic mechanisms of SIRS is the abnormal, exaggerated response of cytokines (TNF-α, IL-6, IL-1). Endotoxins stimulate the production and release of nitric oxide (NO), a vasodilator agent whose growth in a cirrhotic patient (by definition with vasodilator status) has disastrous effects. At the same time, nitric oxide metabolites increase cellular necrosis and platelet aggregability. Proinflammatory aggression factors are numerous, while the level of "protective" anti-inflammatory factors, such as protein C, is low in liver cirrhosis (3).

Impact of infectious complications on the progression of cirrhosis

The association of an infectious complication, sometimes common in other patients, may increase mortality 4 times in patients with liver cirrhosis in comparison with cirrhotic patients without bacterial/fungal infections (10, 11). A retrospective study of more than 11,000 patients

with cirrhosis suggests that there are some predictive factors for death in patients with infectious complications such as: severe liver failure, shock/multiple organ failure, digestive hemorrhage, hepatic encephalopathy, hepatocellular cancer, nosocomial infections (10). Acute renal insufficiency (hepatorenal syndrome, as a particular form of functional renal insufficiency) occurs in 27-34% of patients with decompensated liver cirrhosis, severe liver failure (12, 13); an infectious complication associated to hepatorenal syndrome (preexistent or precipitated by a septic status) increases the mortality rate to 40-50% in liver cirrhosis (10, 12).

Statistical data show an intrahospital mortality of 20-50% for cirrhotic patients with bacterial superinfections, twice higher than in cirrhotics without infections; infections are directly responsible for 30-50% of deaths in liver cirrhosis (14).

Bacterial infections in patients with cirrhosis can be asymptomatic or paucisymptomatic, reason why they must be suspected in any cirrhotic patient with sudden unaccountable deterioration of liver function. Any suspicion of infectious complication requires close monitoring of vital functions: temperature, heart rate, respiratory rate, arterial pressure, physical exam of thorax and abdomen, presence of cutaneous lesions. Mandatory investigations in these cases include hemoleukogram, blood cultures, urine test and urine culture, thorax X-ray, sputum cultures, ascitic fluid/pleural fluid cultures, and abdominal ultrasound.

Spontaneous bacterial peritonitis

Spontaneous bacterial peritonitis (SBP) is the infection of ascitic fluid without organ perforation or abdominal inflammations such as abscesses, acute colecystitis, acute pancreatitis etc. SBP is a frequent and severe complication of cirrhosis, with an incidence of 7-25% in hospitalized cirrhotic patients.

CLINICAL FEATURES

Clinical symptoms are extremely variable in asymptomatic patients (in 30% of cases) progressing to severe deterioration of general status, with the occurrence of hepatoportal encephalopathy, hepatorenal syndrome or death from toxicoseptic shock without obvious cause (1).

The diagnosis of SBP is made by diagnostic paracentesis. This must be performed upon any clinical suspicion of ascitic fluid infection (refractory ascites, abdominal pain, fever etc.) in all admitted patients after the first episode of liver decompensation.

The main SBP diagnostic criteria are based on ascitic fluid microscopy findings (*polymorphonuclear neutrophils* (PMN) count – cut-off value: 250/ml) and *microbial cultures*. Ascitic fluid examination should reveal PMN>250/mm^3 and positive cultures (Gram negative bacilli in 60-80% of cases: *Echerichia coli, Klebsiella Pneumoniae*) (6).

There are two forms of ascitic fluid infection which do not meet all SBP diagnostic criteria, but must be treated similarly:
- neutrocytic ascites with negative culture
- monomicrobial non neutrocytic bacter ascites

Neutrocytic ascites with negative culture – the diagnostic criteria are similar to SBP, but cultures are negative. It is compulsory to rule out other causes outside cirrhosis: peritoneal tuberculosis, acute pancreatitis, and peritoneal carcinomatosis.

Course and prognosis are similar to SBP and, consequently, treatment is identical.

Monomicrobial nonneutrocytic bacter ascites (without neutrophils) is characterized by positive cultures, but with less than 250 PMN/mm^3 in fluid. It may signal the contamination of the ascitic fluid, but also an early form of SBP; clinical course depends on the presence or absence of signs of systemic infection; in patients with signs of infections, prognosis and treatment are similar to SBP.

SBP TREATMENT must be initiated early, immediately after fluid collection and empirically, without waiting for culture results. According to the present standard, 2g of Cefotaxim should be administered every 8h i.v. for 5 days, which is highly effective in approximately 85% of cases, and does not require dose adjustment depending on the degree of liver or renal insufficiency. Intravenous alternatives with similar efficacy are Ceftriaxone 2g every 24h, for 5 days, and Amoxicilin associated to Clavulanic acid 1.2g every 6-8 h, for 2 days (1). In patients who do not present other complications (SDH, encephalopathy, ileus, shock) fluoroquinolons may be administered p.o. for 8 days. The antibiotic must be changed according to the result of the antibiogram.

In cases marked by the occurrence of the hepatorenal syndrome, adjuvant treatment is recommended, some studies showing that associating albumin (1.5g/Kg in the first day, followed by 1g/Kg for another 72 h) with antibiotic is more efficient than the antibiotic administered alone (15).

Administration of early and efficient treatment has allowed us to reach a resolution rate of 90% in spontaneous bacterial peritonitis, with 70-90% intrahospital survival rate.

SBP PROPHYLAXIS

Prophylaxis is recommended in patients at increased risk for asctic fluid infection: upper gastrointestinal bleeding, previous bacterial peritonitis or hypoproteic ascitis (<1g/dl) associated to severe circulatory dysfunction/insufficiency, when administration of Norfloxacin reduces SBP occurrence risk from 61% to 7% (16). In superior digestive hemorrhage, prophylaxis is of short duration and consists of either Norfloxacin p.o./naso-gastric tube for 7 days or a 3rd generation cephalosporine administered i.v. (Ceftriaxone/Cefotaxim). In this context, SBP prophylaxis reduces infectious complication rate, hemorrhage relapse rate, and consequently mortality rate (15% vs. 24%) (16).

In patients with no previous SBP episode the relapse risk is extremely high, reaching up to 70% in the first year, and requires permanent prophylaxis with Norfloxacin 400mg daily. Prophylaxis has considerable results: relapse reduction in the first year from 68% to 20%, with an even more spectacular improvement if only infections caused by Gram negative germs are present (from 60% to 3%) (14).

URINARY TRACT INFECTIONS

In terms of frequency, the infections of the urinary tract are the second most common location, after SBP, for infectious complications in patients with cirrhosis. Their incidence is higher in patients with urinary catheter and in females; also, severe liver insufficiency is often associated with this kind of infections (11).

In non-cirrhotic patients, the etiological spectrum is comparable with that of urinary

infections: Gram negative bacilli and coagulase negative staphylococci (3). The most commonly isolated microorganisms are *Escherichia coli, Klebsiella pneumoniae* and *Enterococcus sporulatus*, but the prolonged use of antibiotic prophylaxis with fluoroquinolons during the last years has determined a significant increase in infections with Gram-positive bacteria, especially in nosocomial infections. Also, an increase in the prevalence of bacterial resistance has been recorded in the case of nosocomial infections (69%) as well as in community-acquired infections (22%) (3). Standard empirical treatment in cirrhotics with urinary infection includes 3rd generation cephalosporins or amoxicillin-clavulanic acid, avoiding fluoroquinolons.

RESPIRATORY INFECTIONS

Microorganisms involved in *community-acquired pneumonia* in patients with cirrhosis are generally the same as in general population, except that in cirrhotics there has been noticed an increased rate of bacteremia, multilobar affectation, renal insufficiency, and septic shock; the course is fatal in almost 15% of cases, mortalitaty being significantly higher than in general population.

The most common causative agent of pneumonia is *Streptococcus pneumoniae*, but other bacteria, normally present in the oral cavity, especially anaerobes, such as *Haemophilus influenzae, Klebsiella pneumoniae, Mycoplasma pneumoniae* or *Legionella* are often involved. In these patients, empirical antibiotic therapy consists in the administration of macrolides (erythromycin) combined with one of the following: cefotaxim, ceftriaxone, amoxicillin-clavulanic acid or quinolons active on pneumococci (17).

Nosocomial pneumonia is caused mainly by Gram-negative bacilli and staphylococci. Patients at increased risk for aspiration pneumonia are mostly those in the ICU, with upper gastrointestinal bleeding (especially those with mechanical tamponade with Blackmore catheter), hepatic encephalopathy or orotracheal tube, situations which favor tracheobronchial aspiration, as well as orotracheal intubation, esophageal tamponade and hepatic encephalopathy. Empirical antibiotic therapy must include 3rd generation cephalosporins (cefotaxim i.v.), carba-penems or piperacillin-tazobactam plus ciprofloxacin or levofloxacin and vancomycin or linezolide (3).

Cirrhotic patients with hydrothorax may develop *spontaneous bacterial empyema* (by analogy with SBP), which occurs in the absence of a pneumonic infection or other obvious cause for empyema) (18,19). Spontaneous pleural empyema occurs in 10-20% of cirrhotic patients with hydrothorax, the main risk factor being SBP (17). The initiation of antibiotic therapy (3rd generation cephalosporins) is indicated even in the absence of bacteriological confirmation, if the pleural fluid contains over 250 PMN/mm^3 (3).

SKIN AND SOFT TISSUE INFECTIONS

Cellulitis and lymphangitis are other infections frequently occurring in patients with cirrhosis as compared to those without cirrhosis. Incriminated risk factors are thin fragile skin, edemas, poor hygiene, malnutrition, frequent hospitalizations, and invasive maneuvers. The involved germs are often *Staphylococcus aureus, Streptococcus pyogenes* and Gram-negative enteric

bacteria, while the incidence of Gram-negative bacilli, such as *E.coli, Klebsiella spp. or Pseudomonas aeruginosa,* has increased (3).

Although skin infections may seem common at a first glance, they may progress to severe cellulitis and necrotizing fasciitis, complications associated with an extremely high mortality, up to 76% (20, 21).

Antibiotic therapy is efficient in most cases with mild forms of cellulites, still with a high degree of recurrence. Antibiotic therapy must be initiated on suspicion of skin infection, as further delay will definitely result in severe forms, where therapeutic intervention is limited, and mortality high.

Standard empirical treatment includes amoxicillin plus clavulanic acid or cephalosporin and ofloxacin, with 83% efficiency in community-acquired infections, but only 50% efficiency in the nosocomial ones (20). Surgical debridement of necrotized tissue is mandatory in necrotizing fasciitis.

MENINGITIS

As with other infectious complications, meningitis has a higher incidences and severity in cirrhotic patients; mortality may reach 50-65% and even exceeds these values in elderly patients or in those with alcoholic cirrhosis (3).

While community-acquired meningitis is mostly caused by pneumococcus and meningococcus, in cirrhotics an increase in the number of meningites caused by *E. coli* and *Listeria* has been observed (3). Another characteristic of meningitis in cirrhosis is the increased risk of recurrence.

Diagnosis of meningitis in cirrhotics is often more difficult, especially in those with hepatic encephalopathy, where neuropsychic symptoms, apparently justified, may confuse and delay diagnosis. Physical examination of the cirrhotic patients with fever syndrome, cephalalgia and neuropsychic disorders must not exclude meningitis. Early diagnosis (it is estimated that in cirrhotic patients this is delayed by 4 times compared to other patients) and empirical antibiotic therapy (with antibiotics that cross the blood-brain-barrier – vancomycin combined with 3rd generation cephalosporins and ampicillin) can help reduce mortality (11).

INFECTION WITH *CLOSTRIDIUM DIFFICILE*

The incidence of *Clostridium difficile (CD)* infection has increased in the past years, while patients admitted to gastro-hepatoenterology units, especially those with liver cirrhosis, show favoring conditions for this complication (3).

What seems intriguing is that this infection occurs less frequently in patients with superior digestive hemorrhage or hepatic encephalopathy, who usually receive antibiotic treatment (an important risk factor in CD infection); this peculiarity may be accounted for by the fact that lactulose (constantly administered in cirrhotic patients with such complications) causes reduction in the production of short chain fatty acids and suppresses CD proliferation (22).

TUBERCULOSIS IN LIVER CIRRHOSIS

Bacillus infection occurs frequently in immunocompromised patients, in chronic alcoholics; by definition, cirrhosis is an important risk for the occurrence of pulmonary or extrapulmonary tuberculosis (23).

Bacillus peritonitis may often be mistaken for SBP (refractory ascites, abdominal

pain etc.), but it usually occurs in patients without significant liver insufficiency. Peritoneal biopsy is often necessary for differential diagnosis, showing multiple disseminated white-yellow nodules, inflammation predominantly with lymphocytes and granulomas.

Cirrhotics with tuberculosis usually have a satisfactory response to tuberculostatic treatment, but with more severe hepatotoxic adverse effects and significantly decompensated liver functions (10).

CONCLUSIONS

Bacterial infections represent an important cause of morbidity and mortality in patients with cirrhosis as a consequence of their immunocompromised status. All patients with liver cirrhosis must be monitored for early diagnosis of infectious complications. Over the past few years, prompt diagnosis and correct antibiotic therapy have determined a significant reduction in mortality due to bacterial infections in patients with liver cirrhosis.

MEASLES VACCINATION IN THE PRESENCE OR ABSENCE OF MATERNAL MEASLES ANTIBODY: IMPACT ON CHILD SURVIVAL

Measles vaccine (MV) has a greater effect on child survival when administered in early infancy, when maternal antibody may still be present. Abay et colab. reanalyzed data from 2 previously published randomized trials of a 2-dose schedule with MV given at 4–6 months and at 9 months of age. In both trials antibody levels had been measured before early measles vaccination. In trial I (1993–1995), the mortality rate was 0.0 per 1000 person-years among children vaccinated with MV in the presence of maternal antibody and 32.3 per 1000 person-years without maternal antibody. In trial II (2003–2007), the mortality rate was 4.2 per 1000 person-years among children vaccinated in presence of maternal measles antibody and 14.5 per 1000 person-years without measles antibody. Possible confounding factors did not explain the difference. In a combined analysis, children who had measles antibody detected when they received their first dose of MV at 4–6 months of age had lower mortality than children with no maternal antibody, the MRR being 0.22 (95% CI, .07–.64) between 4–6 months and 5 years. In conclusion, child mortality in low-income countries may be reduced by vaccinating against measles in the presence of maternal antibody, using a 2-dose schedule with the first dose at 4–6 months (earlier than currently recommended) and a booster dose at 9–12 months of age.(Abay P, Martins CL, Garly ML et al, Measles vaccination in the presence or absence of maternal measles antibody: impact on child survival *Clin Infect Dis*. (2014) 59 (4):484-492.

EXTRAINTESTINAL MANIFESTATIONS AND COMPLICATIONS IN INFLAMMATORY BOWEL DISEASE (Abstract). Inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), doesn't affect only the intestinal tract, but also involve other organs such as: eyes, skin, joints, liver and biliary tracts, kidneys, lungs, vascular system. It is difficult to differentiate the true extraintestinal manifestations from secondary extraintestinal complications. The pathogenetic autoimmune mechanisms include genetic susceptibility, antigenic display of autoantigen, aberrant self-recognition and immunopathogenetic autoantibodies against organ-specific cellular antigens shared by colon and extra-colonic organs. An important role is owned by microbes due to molecular mimicry. This paper reviews the frequency, clinical presentation and therapeutic implications of extraintestinal symptoms in inflammatory bowel diseases. **Keywords:** INFLAMMATORY BOWEL DISEASE, ULCERATIVE COLITIS, CROHN'S DISEASE, EXTRAINTESTINAL MANIFESTATIONS

Ulcerative colitis (UC) and Crohn's disease (CD) are systemic disorders that often involve other organs such as joints, skin, eyes, lungs, biliary tract or urinary system . The etiology is unknown. The main characteristic is an increase of pro-inflammatory cytokines levels: IL-1,-6,-8, tumor necrosis factor (TNF)-α, a decrease of anti-inflammatory interleukins: IL-6,-10 and an increased recruitment of leukocytes to the area of inflammation.

Ulcerative colitis has a chronic intermittent course with periods of remission and relapse. Inflammation is limited to the colon mucosal layer and affects the mucosa in a retrograde and continuous way. An immune mediated mechanism determines an inappropriate immune response against intraluminal antigens affecting individuals who are genetically predisposed. According to the distribution of the inflammation at the mucosal layer, the Montreal Classification was made (tab. I).

TABLE I

Montreal classification of UC

E1	Proctitis (inflammation limited to rectum)
E2	Left-sided disease/procto-sigmoiditis (colorectum distal to splenic flexure)
E3	Extensive disease/pancolitis (proximal to splenic flexure)

Crohn's disease is a chronic relapsing IBD. It is characterised by transmural granulomatous inflammation often involving the ileoceacal part of the gut and leading to a stricturing or even fistulising disease. The ethiology is unknowm, but it was seen an inadequate response of the immune system to the gut microbiota in genetically predisposed people.

The Montreal classification divides CD in three categories according to the localization of the inflammatory process (tab. II).

TABLE II

Montreal classification of CD

Age	Localization	Course of the disease
< 16 years	ileal	Inflammatory
17-40 years	colonic	Stricturing
> 40 years	Ileo-colonic	Penetrating

Prevalence of extraintestinal manifestations (EIM) oscillates between 6-47% of IBD patients (1). In most of the cases they follow the clinical course of gut inflammation, but also may not correlate with disease activity. Some studies suggested an autoimmune reaction regarding an isoform of tropomyosin (Tropomyosin related peptide) detected in skin, joints, eye, biliary epithelium and gut (2) and a common genetic background, HLA system being one of the major genetic markers associated with IBD and EIM. There is a correlation between CD and HLA-A2,-DR1, DQW5 and between UC and HLA-DRB1*0103, B27, B58 (3, 4). Also the genetic ground can guide about the risk of extraintestinal manifestations (tab. III) (3, 5, 6).

TABLE III

HLA system and the risk of EIM

HLA- B8, DR3	primary sclerosing cholangitis
HLA- DRB1*0103 (DR103)	ocular, articular manifestations
HLA B27, B58	uveitis
HLA B27	ankylosing spondylitis
1031 C TNF-α	erythema nodosum
CARD 15, NOD2 gene	sacroiliitis

TABLE IV

Classification of EIM

Extraintestinal immune-related manifestations of IBD	• arthritis • erythema nodosum • pyoderma gangrenosum • aphtous stomatitis • iritis/uveitis	• the same pathogenic mechanism • associated with intestinal inflammatory activity
Autoimmune disorders associated to IBD	• ankylosing spondylitis • primary sclerosing cholangitis • polymyositis • primary biliary cirrhosis • alopecia areata • thyroid disease	• major susceptibility to autoimmunity • independent of IBD
Extraintestinal complications	• osteoporosis • biliary/urinary lithiasis • anemia • tromboembolic events • amyloidosis • fatty liver	• metabolic or anatomical abnormalities due to IBD • inflammatory activity • medication use • poor nutrient intake/absorption

Extraintestinal manifestations can be devided in three categories: extraintestinal immune-related manifestations of IBD, autoimmune disorders associated to IBD and extraintestinal complications according to the pathogenic mechanism and the relation between intestinal inflammatory activity and the presence of this secondary disorders (tab. IV) (7).

1. **Musculoskeletal manifestations**

Inflammatory arthropathies are the most common extra-intestinal manifestations of IBD and take part of a wider group named spondylarthropathies. Joint manifestations can precede, be synchronous or can manifest afterward IBD.

Peripheral arthropathies appear can pre-date the onset of the gut clinical signs. Their prevalence in UC is smaller (5-10%) than in CD (10-20%) (8). The main characteristic is their non-erosive, non-deforming pattern. *Type1***:** pauci-articular (less than five joints) is defined by migratory non-deforming and non-erosive large-joint arthropathy predominantly of the lower limbs. It is associated with HLA B27, -B35, HLA-DRB1-0103 in up to 65% of the patients. The acute episode is self limiting (mean duration is 5 weeks) and runs in parallel with the IBD. *Type 2***:** polyarticular (more than five joins affected) characterised by symmetrical persistent small joint poly-arthropathy. The course is independent of the underlying IBD and can last for several months (8). The genetic background is strongly correlated with HLA B44, MHC class I chain-like gene A (on chromosome 6) (4, 9).

The etiology is based on genetic predisposition and the exposure to luminal bowel contents. It has been demonstrated a dysbiosis with a decreasing quantity of bifidobacteria, lactobacilli, *Escherichia coli*, an increase of facultative flora (*Staphylococcus, Klebsiella*, *Proteus*), a modification of the colonocyte's cell receptor maturity of mucus (decreased staining intensity by lectins) and a cytokine imbalance with an increase of proinflammatory markers (IL-1,6,8, TNF α) (10).

Axial arthropaties are not correlated with disease activity of IBD. Sacroiliitis is non-progresive and is not associated with HLA B27. This form is associated with enthesitis, tenosynovitis, dactylitis even in the absence of arthritis (11). Bacteria and bowel inflammation plays a decisive role in the pathogenesis of IBD-associated ankylosing spondylitis, fact demonstrated by ileocolonoscopy in patients with idiopathic spondylarthropathies (12).

Osteoporosis is an extraintestinal complication of IBD. The main role in the ethiopathogenesis is assumed to the connection between OPG-RANKL-RANK (13). Osteoclastogenesis is induced by a surface receptor (RANK) located on osteoclasts. Its ligand (RANKL) is induced by proinflammatory cytokines. On the other hand, osteoblasts produce osteoprotegerin (OPG) which prevents ligation of RANKL to RANK, so the bone loss is stoped. It has been proved that alendronate improved spine bone density in IBD patients (14).

Osteomalacia is also a complication of IBD. It is determined by a prolonged and severe vitamin D deficiency. Often appear after multiple intestinal resections in severe cases of CD (15).

2. **Hepatobiliary manifestations**

It can or cannot be related to immunological disorders or may depend on side effects of therapy used for IBD.

Primary sclerosing cholangitis (PSC) is a chronic, slowly progressive cholestatic

disorder characterized by inflammation and fibrosis of intrahepatic / extrahepatic bile ducts. 2-7% of patients with UC develop PSC. It is a premalignant condition for cholangiocarcinoma and determine a higher risk of colonic dysplasia/carcinoma due to folate deficiency, long periods and asymptomatic colitis or changes in bile salts (16, 17). High titres of autoantibodies to neutrophils (pANCAs) were found in the serum of these patients (18) and also they have, in a proportion of 70%, HLA DR3, B8 haplotype.

Hepatobiliary complications include: cholelithiasis, more frequent in CD and caused by the malabsorption of bile salts from the inflamed terminal ileum, fatty liver due to steroid therapy or poor nutrition, liver abcesses, portal vein thrombosis, suppurative pylephlebitis.

3. **Mucocutaneous manifestations**

Mucocutaneous manifestations can be divided in three classes of injuries relaying on the ethiopathogenic mechanism (tab. V).

TABLE V

Classification of mucocutaneous manifestations

Granulomatous disorders	• perianal/peristomal ulcers and fistulas • metastatic CD • oral granulomatous ulcers
Reactive skin manifestations of IBD	• aphthous stomatitis • pyoderma gangrenosum • erythema nodosum • Sweet's syndrome
Nutritional- deficient cutaneous manifestations	• acrodermatitis enteropathica

Granulomatous lesions and IBD have the same histological pattern. Perianal / peristomal ulcers and fistulas frequently appear in patients with CD (50%) and can be external or internal (entero-cutaneous) (19). In the group of external manifestations we can find: perianal erythema, abscesses and perianal complex fistulae. Internal fistulas are more serious and require a prompt systemic medication and even surgery. Metastatic CD are represented by subcutaneous nodules or ulcers which appear especially at the lower limbs (20). Oral lesions are aphthous ulcers which appear in 10% of patients with UC and in 20-30% in those suffering from CD.

Reactive skin manifestations of IBD usually are diagnosed in parallel with intestinal disease activity. *Aphthous stomatitis* follows the colonic localization of IBD. The histological pattern show a lymphohistiocytic infiltrate located in the lower derme. The disease can be associated with arthritis and correlated with IBD acuteness.

Pyoderma gangrenosum may run an independent course of the underlying IBD activity. Commonly involves the skin with a predilection for the lower limbs, but also may occur around surgical stomata or in any area of the skin. Macroscopically it is represented by discrete pustules which coalesce and form ulcerations with central necrosis and with erythematous or violaceous edges. Histologicaly there is a deep suppurative folliculitis with diffuse neutrophilic infiltration and dermolysion. It can exist in association with other extraintestinal manifestations such as arthritis, ery-

thema nodosum (21). *Erythema nodosum* appears as raised, warm, tender erythematous nodules tipically in the pre-tibial areas. Histologicaly it is a septal panniculitis due to immune complex deposition. It was proved a genetic association between erythema nodosum and a certain HLA region of chromosome 6 (HLA B) (22). Flares occur concurrently with gut exacerbations. The disease normaly heals without ulcerations and resolve spontaneously within 3-6 weeks. *Sweet's syndrome* is a neutrophilic dermatosis which appears as painful erythematous nodules or plaques. It is often associated with fever and leukocytosis.

Nutritional - deficient cutaneous manifestations include acrodermatitis enteropathica determined by zinc deficiency. It has a clinical pattern as a psoriasis erythema.

4. **Ocular manifestations**

There are two kinds of manifestations depending on their immunopathogeny. Immune-related conditions such as: episcleritis, scleritis, uveitis, corneal disease or related to drug exposure: cataract, glaucoma (table VI). A high risk for developing these conditions is the presence of genotypes HLA B27, B58, DRB 10103. Usually are flaring and subsiding at the same time as the bowel inflammation (22, 23) (tab. VI).

TABLE VI
Classification of eye disorders

immune-related ocular manifestations	• episcleritis • scleritis • uveitis • corneal disease
ocular manifestations related to drug exposure	• cataract • glaucoma

Episcleritis is the most common extraintestinal manifestation, mainly in CD patients. It appears at the same time with active gut disease. Clinically we can find acute redness, irritation, burring, tender to palpation. The treatment refers to topical steroids and also the therapy of the underlying intestinal condition.

Uveitis appears more common in females and more often bilaterally. It may not parallel gut disease activity and sometimes can precede the diagnosis of IBD. It need a prompt therapy because can lead permanent damage to the eye.

Corneal disease includes ***conjunctivitis*** which is quite frequent.

Use of steroids can lead to ***cataract*** and the malabsorption of vitamin A can determine ***keratopathy*** or ***night blindness***.

5. **Pancreatic manifestations**

Pancreatic manifestations can take two forms: acute or chronic pancreatitis. Acute pancreatitis is induced by drugs such as salycilates, azathioprine, 6-mercaptopurine. Usually it has a mild course with a remission of the inflammatory processes after discontinuing the therapy. In 40% of CD patients were found pancreatic autoantibodies (24). Chronic pancreatitis is characterized by a decreased exocrine function due to circulating inflammatory mediators or to autoantibodies against pancreatic tissue (25, 26). Patients with IBD have modifications of intrapancreatic duct (26).

6. Thromboembolic events

Thromboembolic events have an incidence between 1.2% to 6.1%, but some necropsy studies found out that this incidence is much higher being up to 30% (27). The pathogenesis refers to hyperhomocysteinemia due to the deficiency of vitamin B_6, B_{12} (malabsorption) or folate (malabsorption, use of folate-inhibiting drugs such as methotrexate/ sulfasalazine) (28). One study found a significant higher prevalence of factor V Leiden in the group of IBD patients (29). Other events which participate at the procoagulatory status are: an increase frequency of antiphospholipid antibodies, higher levels of lipoprotein (A) (27).

7. **Anemia**

Anemia is considered to have many pathogenic ways: chronic intestinal bleeding, iron malabsorption in duodenum and upper jejunum, vitamin B12 malabsorption, folate deficiency due to malabsorption or to side effects of drugs. Also the high level of proinflammatory cytokines can make a diversion of iron traffic to reticuloendothelial system (30). A lot of drugs used for the treatment of the current gut disease can have direct myelosuppressive affect (sulfasalazine, azathioprine, 6-mercaptopurine) (30).

8.**Urinary system manifestations**

IBD patients present quite frequent minimal, subclinical, glomerular inflammatory changes. Interstitial nephritis and tubular proteinuria is often attributed to CD (31). Glomerulonephritis can lead to nephrotic syndrome and renal failure and is directly related to the activity of the bowel disease. Urinary complications include nephrolithiasis and urinary tract fistulas. Nephrolithiasis appear more frequent in CD than in UC (32). The most common are calcium-oxalate stones due to fat malabsorption that cause a lack of free calcium and increased oxalate absorption.

Renal amyloidosis appers more often in ileal CD. The ethiology is unclear, but is related to chronic inflammation and acute phase reaction proteins (33).

9. **Pulmonary manifestations**

Usually pulmonary disease parallels the bowel intestinal activity. The most common manifestation is bronchial inflammation and suppuration with or without bronchiectasis. The etiopathogeny includes: the same embryological origin of the lung and gastrointestinal system by ancestral intestine (34), similar immune systems in the pulmonary and intestinal mucosa (35), the presence of circulating immune complexes and auto-antibodies.

Half of patients with CD have ***subclinical alterations*** of the lungs without pulmonary symptoms (36). Abnormal pulmonary function tests are found in 42% of IBD patients without respiratory symptoms or radiograph findings (37). Lung inflammation correlates with bowel disease activity.

Airway diseases include upper-airway obstruction, tracheobronchitis, chronic bronchitis, granulomatous bronchiolitis, bronchiectasis, asthma and acute respiratory failure. The most frequently appear bronchiectasis (37). Bronchoscopy shows diffuse inflammation of the trachea and bronchi and the biopsy reveals metaplastic disorders in the epithelium and granulomatous infiltration.

Lung parenchymal diseases include bronchiolitis obliterans with organizing pneumonia (BOOP), unspecified interstitial lung disease, noncaseating granulomatous inflammation and fibrosis, parenchymal nodules and granulomata, alveolitis and alveolar consolidation. The lung biopsy shows acute alveolitis, granulomatous lymphocytic infiltration of the interstitium and

of the walls of small arteries with slight interstitial fibrosis.

Pleural diseases include pneumothorax, pleural thickening, pleuritis and pleural effusion (38). There is an association between pleural effusion and pericarditis (39). The pleural complications of CD may run an independent course and may be present at the time of inactive bowel disease.

Drug-related lung disease can be interpreted as complications. Sulfasalazine and mesalamine can induce interstitial disease, eosinophilic pleuritis/ pneumonia or even asymptomatic lung injury(40). After the use of azathioprine or 6-mercaptopurine has been reported interstitial pneumonitis, BOOP, chronic pneumonitis /fibrosis and pulmonary edema (41). Methotrexate can cause interstitial pneumonitis, granuloma formation and bronchiolitis (42). Biological therapy with anti TNF drugs (infliximab, adalimumab, certolizumab) is associated with the presence of opportunistic infections due to the suppression of T cell-mediated immunity or can directly affect the lung parenchyma causing acute respiratory distress syndrome, diffuse alveolar hemorrhage, nonbronchiolitis inflammatory nodular pattern of the lung and interstitial lung disease. Frequently appear or is reactivated latent tuberculosis (43).

10. **Cardiovascular manifestations**

Heart involvement is rare. It is seen more frequently in men and in those with ulcerative colitis. These manifestations are not related to the activity of the bowel disease. Cardiac involvement may present as pericardial effusion, myopericarditis and conduction defects. Pericarditis is the most common manifestation in CD.

Other patients with Crohn's disease or ulcerative colitis suffer from vasculitis. There is a relation between Takayasu's arteritis and Crohn's disease due to cross-reacting antibodies against gut mucosa and aortic tissue. Some patients developed thrombotic complications by activating the coagulation system and it manifest like atrial thrombi, embolism of the pulmonary arteries, myocardial infarction and disseminated intravascular coagulopathy. Furthermore, a few cases were reported about atrio ventricular blocks, amyloidosis of the heart, dilative cardiomyopathy and endomyocardial fibrosis in patients with chronic inflammatory bowel disease (44).

11. **Neurological manifestations**

It includes central and peripheral nervous system involvement. Peripheral neuropathy is one of the most common complications. It has also been found an inflammatory myopathy. Cranial neuropathies include the Melkersson-Rosenthal syndrome, optic neuritis, and sensorineural hearing loss (45-47). Ischemic stroke depends on few mechanisms, including large/small artery disease, paradoxical embolism, endocarditis, vasculitis. Thrombosis of the dural sinus and cerebral veins are as frequent as arterial stroke in IBD. Multiple sclerosis has been frequently associated with IBD (48). Almost 50% of IBD patients have asymptomatic white matter lesions. Other central nervous system manifestations are represented by: a slowly progressive myelopathy, epidural and subdural spinal empyema, seizures and encephalopathy (49, 50).

CONCLUSIONS

Beside the classic gastrointestinal manifestations, a large number of IBD patients present with extraintestinal manifestations which can affect every site of the body. Extraintestinal manifestations may produce greater morbidity than the underlying intes-

tinal disease and may even be the initial presenting symptoms of the IBD. Some of these disorders are more frequent associated with active colitis (joint, skin, ocular and oral manifestations), others are related to small bowel dysfunction (cholelithiasis, nephrolithiasis, and obstructive uropathy) and few are nonspecific manifestations (osteoporosis, hepatobiliary disease, and amyloidosis). The distinction between disease and treatment side effects can be extremely difficult and may sometimes be impossible. Early recognition of these extraintestinal manifestations should help guide therapy that will reduce overall morbidity in affected patients.

ALOPECIA - A CHALLENGE FOR DERMATOLOGISTS (Abstract): Alopecia is a loss of hair in the areas where it normally grows. It has to be distinguished from atrichia, the congenital absence of hair due to the absence of hair follicles, and hipotrichosis, scarcity or absence of hair in some congenital diseases. Alopecia is either scarring, when the skin appears atrophic, scaling, and smooth and the hair follicles are absent, or nonscarring, when hair loss is not accompanied by the destruction of hair follicles. This paper is a review of all types of alopecia and their features in an attempt to make them easier to identify and differentiate.
Keywords: ALOPECIA, ANDROGENIC ALOPECIA, ALOPECIA AREATA.

Hair is an esthetic element with important psychosocial impact in both women and men, regardless of age. All hair disorders are actually hair follicle disorders.

Alopecia is a loss of hair in the areas it normally grows. It has to be distinguished from atrichia, the congenital absence of hair due to the absence of hair follicles, and hipotrichosis, scarcity or absence of hair in some congenital diseases.

Alopecia is either scarring (tab. I), when the skin appears atrophic, scaling, smooth, and the hair follicles are absent, or nonscarring, when hair loss is not accompanied by the destruction of hair follicles; nonscarring alopecia may be localized or diffuse (1, 2, 3) (tab.II).

Sometimes, alopecia and hypotrichosis together with other skin and adnexal changes are part of a congenital syndrome.

The growth cycle of the hair follicle differs depending on body area; thus, scalp hair has 3 phases of unequal duration: anagen (3-5 years), catagen (2-3 weeks) and telogen (3-4 months). Approximately 85% of hair follicles are in the growth phase (anagen) and 70-100 hairs are shed daily (telogen). Hair follicles of the eyebrows, trunk and limbs have a similar duration of anagen and telogen phases (6 months). The growth cycle of the hair follicle is influenced by a number of inhibitory and stimulatory factors.

The onset of anagen phase recapitulates the molecular events during hair follicle development, and insulin like growth factor 1 (IGF-1) and fibroblast growth factor 7 (FGF-7) have important roles in their development and cycling. The length of hair is directly proportional to the duration of

anagen cycle, and the cessation of this cycle is controlled by fibroblast growth factor 5 (FGF- 5), expressed in the hair follicle prior to the end of this phase, and also by the system of the epidermal growth factor receptors (EGF) .

The catagen phase is the phase during which the hair follicle goes through a highly controlled process of involution, reflecting the stimulation of apoptosis in the majority of follicular keratinocytes and in some follicular melanocytes. Thus, follicular melanogenesis ceases. Dermal papillae condense and move upward, coming to rest underneath the hair follicle bulge and ceasing its cycle. There is a programmed destruction of a few hair follicles by the action of an inflammatory cell infiltrate.

During the telogen phase the hair shaft matures which is eventually shed from the follicle. The percentage of hair follicles in telogen phase varies substantially according to the body region. Later, the hair follicles reenter the anagen phase and the cycle is repeated (4).

TABLE I
Classification of alopecia

Nonscarring alopecia	**Scarring alopecia**
- androgenic alopecia - alopecia areata - telogen effluvium - drug-induced alopecia - toxic alopecia - postradiation therapy alopecia - infectious disease - collagenoses - renal failure - deficiency disorders - dysthyroidism	- primary lymphocytic: • chronic discoid lupus erithematosus • lichen planopilaris • classic pseudopelade of Brocq • keratosis folicularis spinulosa decalvans • alopecia mucinosa - primitive neutrophilic: • folliculitis decalvans • dissecting cellulitis/folliculitis - primitive mixed: • keloid acne of the neck • pustular erosive dermatitis - secondary • defective development • primitive or secondary malignant neoplasms • infections • physical factors

Nonscarring alopecia

Androgenetic alopecia (AGA) is the most common form of nonscarring alopecia, accounting for 95 % of all cases of alopecia. It affects 50% of men by age 50 years, 13% of premenopausal women, and 37% of menopausal women. It is characterized by progressive, genetically determined hair loss, and occurs in most men with hairline recession at the temples and vertex, and also in some women (5). It begins in the frontotemporal region or on the vertex with a 10 time-decrease in hair diameter and hair diameter variations. In men, there is a family

history of AGA in the first or second degree relatives, while in women AGA is associated with micropolycystic ovary syndrome (MPCOS), hormonal treatments, or ovarian tumors. AGA is progressive and the rate of hair loss is unpredictable.

In female, Ludwig classification is used to differentiate the three clinical forms of AGA (6, 7):

1. diffuse thinning in midline part;
2. progressive thinning in midline part with preservation of frontal hairline;
3. oval patch of hair loss with antero-posteior long axis, surrounded by a round band of normal density hair.

In women, vortex alopecia, male-pattern baldness or diffuse alopecia are not very common (5).

TABLE II

Classification of alopecia

Temporary/reversible alopecia	**Permanent/irreversible alopecia**
- diffuse acute: • acute telogen effluvium • drug-induced alopecia • toxic alopecia • postradiation therapy alopecia • acute anemia - diffuse chronic • androgenetic alopecia • nonandrogenetic alopecia - chronic telogen effluvium - drug-induced alopecia - renal and hepatic insufficiency, dysthyroidism - circumscribed: • alopecia areata • traumatic: trichotillomania • postinfectious: syphilis • in chronic dermatites: - chronic eczema, psoriasis	- primitive limphocytic: • chronic discoid lupus eritematosus • lichen planopilaris • classsic pseudopelade of Brocq • keratosis folicularis spinulosa decalvans • alopecia mucinosa - primitive neutrophilic: • folliculitis decalvans • dissecting cellulitis/folliculitis - primitive mixed: • keloid acne of the neck • pustular erosive dermatitis - secondary • defective development • primitive or secondary malignant neoplsams • infections • physical factors

In males, it is used Hamilton-Norwood classification (8).

Laboratory investigations to be performed are: hormone testing (free testosterone, dehydroepiandrosterone sulphate, prolactin, luteinizing hormone); ovarian and adrenal gland ultrasound; serum iron and ferritin; complete blood test; trichogram: hair strands uneven in diameter; scalp biopsy; trichoscanning; phototrichogram.

In men a systemic treatment with 5-alpha-reductase inhibitors such as Finasteride 1 mg/day, 3-6 months, or Dutasteride, and in women a systemic antiandrogen treatment with Diane 35, 6-12 months alone or associated with Androcur, 6 months, spironolactone, flutamide may be

initiated.

In both cases a series of topical solutions can also be used: Minoxidil 2% or 5%, Dercos-Aminexil, Chronostim; shampoos: Anaphase, Dercos; in severe cases hair implant and camouflaging techniques are recommended.

Alopecia areata (AA) is a nonscarring inflammatory alopecia of unknown cause, with an unpredictable course, a prevalence of 0.1% among the population, and twice more common in women.

Etiological hypotheses:

- psychosomatic factors: emotional stress (9);
- infectious factors: cytomegalovirus;
- genetic factors: there is a 55% concordance rate in monozygotic twins, compared to no concordance in dizigotic twins (10);
- endocrine factors: association of myxedema, diabetes mellitus type 1;
- chemical factors: interferon alfa, ribavirin, biological agents;
- association with atopy in 10% of cases;
- AA is considered a T-lymphocyte mediated autoimmune disease.

Hair strands, path gnomonic for AA, have an "exclamation mark" appearance, 1 cm long, the distal end is darker and rough, and proximal shaft is depigmented, narrow, with small, poorly formed root. Their presence suggests active phase of the disease, being absent on old alopecia areata patches (11).

Clinical forms

AA is clinically characterized by the presence of round non-inflammatory hair loss areas that may enlarge and form bizarre patterns. Recent patches sometimes are discretely erythematous or present depression in the skin, but usually the skin is normal in appearance, but hypotonic (Jacquet sign) .

Ophiasis AA is characterized by hair loss patches that begin in the occipital region and then extend along the edge of the hairy scalp, and partially or completely wrap the scalp (fig. 1).

Fig. 1. Ophiasis alopecia areata

AA of the beard appears either independently or associated with that of the scalp.

Alopecia totalis affects the entire scalp and *alopecia universalis* covers the entire body.

Laboratory investigations to be performed are: trichogram: dystrophic hairs; hormonal and immunological tests for the detection of a possible autoimmune thyroid disease; tests for the detection of associated atopy; histopathology: atrophic hair follicle and the presence of perifollicular lymphocytic infiltrate; antibody determination: antinuclear, antithyroid, antiparietal cell, anti-endothelial.

Although there is no causal treatment, a range of therapies with beneficial effects can be used.

The goals of treatment are a cosmetically acceptable hair regrowth and a long-term

therapeutic effect without severe side effects (12,13,14). Therefore, the following can be used: immunosuppressive therapy: corticosteroids (inhibit the production of proinflammatory cytokines), cyclosporine A (specific inhibitor of CD4+ lymphocyte activation by its action on calcineurin), macrolide immunosuppressants (inhibition of calcineurin), photochemotherapy; topical immunomodulatory therapy which induces production of contact dermatitis (DNCB = dinitrochlorobenzeon, SADBE = squaric acid dibutylester, DPCP = diphenylcyclopropenone); minoxidil; dithranol(15).

Telogen effluvium (TE) is characterized by temporary diffuse hair loss as a result of shortened hair cycle and an increased number of hairs are in telogen phase. Thinning of hair on the scalp is diffuse, sometimes being predominant in the parietal area. It is noted when 20-25% of the scalp hair has falled out.

Of the causative factors we mention: iron deficiency anemia, hyper- or hypothyroidism, delivery, inadequate diet, oral contraception or its discontinuation, medications: hormones lipid-lowering agents, chemotherapy, antihypertensive drugs, psychotropic drugs, anticonvulsants, accidental exposure to toxic substances, chronic renal insufficiency, secondary syphilis (11).

Headington has described 5 fuctional types of ET:

- immediate anagen release and telogen entry: psychological stress;

- delayed anagen release: after pregnancy (during pregnancy - anagen is prolonged);

- short anagen phase: idiopathic shortening of anagen;

- immediate telogen release: minoxidil shortens the normal telogen to stimulate hair follicles to cycle into anagen;

- delayed telogen release - prolonged telogen followed by transient anagen (usually in animals, occasionally in humans).

Laboratory investigations to be performed are: trichogram, blood tests, total body iron, liver tests, kidney tests, thyroid tests, tricoscanninge.

As part of treatment, avoidance of stress and systemic exposure to toxic substances is recommended. Systemic treatment includes zinc, biotin, cysteine, essential fatty acids supplements and correction of existing hormonal imbalances. The use of topical hair loss products is also recommended (16).

Scarring alopecia

Primitive lymphocytic scarring alopecia

Chronic discoid lupus erythematosus is two times more common in women over 40 years. It is characterized by erythematous, squamous plaques with irregular extension on the scalp and pruriginous scars. In the colored people dyschromias and, more rarely, calcification at plaque level may appear. With time, these plaques may undergo malignant transformation to squamous cell carcinoma (17). As treatment, systemic and topical corticosteroids, synthetic antimalarials, acitretin, dapsone, cyclophosphamide, cyclosporine, and methotrexate may be used.

Classic pseudopelade of Brocq has a higher frequency in women aged 30-50 years. Darier and Civatte talk about this condition as about a folliculitis, while Rabut, Duperre, Leclerq support the theory of pseudopelade state according to which there can be many causes (lichen planus, lupus) inducing the same effect. Initially, there are small isolated atrophic plaques that progressively enlarge, become irregu-

lar, and have a tendency to confluence, giving them the "footprints in the snow" appearance. The plaques have polycyclic or scalloped edges. Alopecia plaque is white, smooth, clean, slightly depressed, scarring, and hairs fall out imperceptibly, without prior skin lesions (fig. 2). Disease progression is slow, and often remits spontaneously. The treatment is usually ineffective. Autografting from unaffected areas and scar reduction with tissues expansion can be performed.

Fig. 2. Classic Brocq pseudopelade

Lichen planus is an idiopathic inflammatory disease affecting the skin, hair and nails. There are 3 clinical variants of lichen that can cause alopecia: lichen planopilaris, frontal fibrosing alopecia, Graham Little syndrome.

Recent lichen planopilaris lesions are purple erythematous-squamous papules that, over time, are covered by follicular hyperkeratotic plugs that eventuate into scars. Subsequently, plugs shed and leave a white, smooth, atrophic scar. In the hair loss area the follicular orifices are absent, and at its margin the hait pull test is positive. In the presence of inflammation, the treatment implies the use of high-potency topical corticosteroids.

Hydroxychloroquine, acitretin, and cyclosporin can also be administered.

Postmenopausal frontal fibrosing alopecia is characterized by the loss of follicular orifices, occurrence of erythema and follicular hyperkeratosis located in the frontal region, and a gradual progression.

Graham Little syndrome occurs in women aged 30 to 70 years, and is characterized by scarring alopecia of the scalp and nonscarring axillary and pubic alopecia. A few months later follicular keratosis develops on the trunk and limbs. The therapeutic choice is the administration of cyclosporin (18).

Neutrophilic primitive scarring alopecia

The etiology of folliculitis decalvans of the scalp is unknown; it may occur around the onset of puberty. Typically, the bacteriological examination of pustular secretions identifies *Staphylococcus aureus*. Clinically, initially seen are follicular pustules that evolve and heal with the formation of alopecia plaque surrounded by scales and new follicular pustules. Treatment consists in antibiotic therapy to eradicate *Staphylococcal aureus*.

Dissecting cellulitis of the scalp usually occurs in black men aged 18 to 40 years. Its cause is unknown. It is characterized by the occurrence of perifolliculitis capitis with the formation of superficial and deep abscesses in the dermis that have the tendency to fistulizing and healing with extensive scarring (fig. 3). It can be associated

Fig. 3. Dissecting cellulitis of the scalp

with two other diseases that cause pilosebaceous system obstruction: hidradenitis suppurativa hydradenitis and acne conglobata. In time, it can transform into squamous cell carcinoma. Treatment with systemic retinoids, general corticotherapy, and later local cortico-therapy with antibiotics is recommended.

Mixed primitive scarring alopecia

Erosive pustular dermatosis occurs in the elderly and is of unknown etiology. Grattan conducted a study on a group of 12 patients with erosive pustular dermatosis and found the presence of some common factors: local trauma and sun exposure. It can be associated with androgenetic alopecia. Initially, a small area of the scalp becomes erythematous, covered by crust and then superficial pustules occur on the area that became erosive. Active areas coexist with areas of scarring. The literature mentions the likelihood of malignant transformation to squamous cell carcinoma. Initial treatment relies on high-potency topical corticosteroids and later on moderate-potency ones, the use of sunscreen, zinc supplements, calcipotriol.

Keloid acne the neck is characterized by chronic perifollicular inflammation, more intense in the isthmus and infundibulum, with sebaceous gland loss. In advanced stages there is total destruction of the pilosebaceous system; it heals with scarring.

Secondary scarring alopecia may occur due to:

- as a result of the action of some physical factors: radiodermatitides, mechanical trauma, postsurgery, thermal/electrical burns, traction alopecia;
- diseases characterized by marked skin fibrosis: scleroderma, lichen sclerosus, porphyria cutanea tarda, chronic graft-versus-host disease;
- granulomatoses: sarcoidosis, necrobiosis lipoidica, granulomatous infections;
- infectious causes: bacterial: folliculitis, carbuncle/boil; fungal: kerion celsi, scab, tinea capitis (very rare); viral: herpes zoster, chickenpox, HIV; protozoa: leishmaniasis; treponema: syphilis; mycobacteria: tuberculosis;
- benign tumors: cylindromas;
- primitive malignancies: basal cell carcinoma, squamous cell carcinoma, cutaneous T-cell lymphoma;
- malignancies secondary to: kidney, lung, gastrointestinal tumors, lymphomas, leukemias (4,19).

LOW VITAMIN C LINKED TO INTRACEREBRAL HAEMORRHAGE

A group of researchers leaded by Dr. St Vannier, from Pontchaillou University Hospital, Rennes, France, shows that vitamin C depletion was more common among intracerebral haemorrhage (ICH) cases than controls. The case-control study was performed on 135 subjects, with a mean plasma vitamin C concentration of 45,8 μmol/L and showed that the vitamin C level was significantly lower in 65 patients with ICH than in 65 controls. Also, the study found that hypertension ($p = 0,008$), alcohol consumption ($p = 0,023$), and overweight ($p = 0,038$) were the most important risk factors for ICH. The researchers presented that vitamin C deficiency may play a role in the aetiology of high blood pressure and may increase the risk for atherosclerosis and heart diseases. The study reveals this vitamin contributes to collagen biosynthesis and regulation and the deficiency of vitamin C is responsible for unstable and dysfunctional collagen which may lead to haemorrhages. The authors show that the hospitalization length was significantly shorter for patients with a normal concentration of vitamin C than for those with a lower level, and the risk for complication/related infections was higher for those with vitamin C deficiency. ASPECTS OF MOLECULAR MECHANISMS IN MYOCARDIAL HYPERTROPHY, PARTICULAR MORPHOLOGICAL CHANGES AND CELL BIOENERGETIC CHARACTERISTICS IN PATIENTS WITH DILATED CARDIOMYOPATHY (Abstract): **Aim:** To present the particular morphological aspects of hypertrophied myocardium by determining protein expression profile, the role of creatine kinase in cardiac cell function and mitochondrial respiration using endomyocardial biopsy samples obtained at cardiac catheterization in patients with dilated cardiomyopathy (DCM). **Material and methods:** The study included 43 DCM patients (37 men and 6 women, mean age 34±8.6 years). Protein content in myocardial samples was determined by quantitative immunoblotting and electrophoresis, morphometric indices were evaluated with a JEM-100C electron microscope, and mitochondrial respiratory parameters were determined with a Clark electrode in an oxigrtaphic cell. **Results:** The study of the expression of hypertrophic protein markers showed increases in the amount of tubulin on average by 42%,desmin by 33%, and skeletal myosin beta-isoform by 20%, and of smooth muscle proteins – alpha-smooth muscle actin and SM22 on average by 1.5 times. In all DCM patients C-reactive protein (CRP) level was on average 52% and that of myosin light-chain kinase (MLCK) 70% higher. The morphometric study showed variable characteristics of cardiomyocytes in the entire patient group, particularly bizarre and oversized nuclei, determining us to divide the patients into two groups. The electrophoresis analysis of total creatine kinase fraction revealed significant alterations in the expression of creatine kinase isoenzymes. Mitochondrial respiration rate after addition of creatine was very low. **Conclusions:** We found a high content of myosin light-chain kinase and CRP in the myocardium of patients with DCM, proving their role in hypertrophy; and this can be used in the differential diagnosis of myocardial hypertrophy as a consequence of cardiomyocyte hypertrophy and a result of the fibrotic process. Energy disturbances are significantly more pronounced in patients with DCM, with a more significant cardiomyocyte hypertrophy and an obvious increase in the size of nuclei. **Keywords:** CARDIOMYOPATHY, HYPERTROPHIC CARDIOMYOCYTES, MITOCHONDRIA

In DCM, disease accompanied by dilatation of cardiac chambers and severe myocardial contractility disturbances, cardiomyocytes are subjected to a substantially increased mechanical load (1, 2) The changes in myocardial structure include a

percentage of cardiomyocyte apoptosis, impaired segmentation and coordination of myocyte distribution in the ventricular walls, interstitial fibrosis and hypertrophy of the remaining functional muscle cells (3). Lately, there have been huge efforts towards establishing the molecular mechanisms of cardiac hypertrophy. The core element of cardiomyocyte hypertrophy (CMC) is the forming of the contractile apparatus – sarcomerogenesis (4, 5). It is assumed that smooth muscle and nonmuscle proteins play the key role in the forming of presarcomere structures, expressed in CMC, especially myosin light-chain kinase (MLCK) and the alternative product of MLCK genetic locus -myosin- CRP agglutinated protein (4, 6). Experimental models showed that MLCK fermentation activity is required for myofibrillar assembly in the hypertrophic response of cardiomyocytes (CMC).

Existing data advocate that the multiple products of MLCK genetic locus are involved in the forming of contractile structures of CMC in animals. It is logical to assume that similar processes also occur in the human heart, in cardiac hypertrophy, and especially in cardiomyopathies, but alas, papers on this topic in the literature are lacking. Valuable information on the probable mechanisms of CMD evolution at sub cellular level has been acquired by using different biochemical research methods. Changes in the activities of key myocardial cell enzymes in patients with DCM, including respiratory chain enzymes, creatinine kinase system isoenzymes were detected. The decreased phosphocreatine (PCr) content, redistribution of creatine kinase isoenzymes and of myosin was demonstrated (9). However, in the literature, there are only isolated works focused on studying the role creatinine kinase isoenzymes and cellular respiration parameters in the pathogenesis and clinical course of CMD.

MATERIAL AND METHODS

The study included 43 DCM patients (37 men and 6 women, mean age 34±8.6 years). Protein content in myocardial samples was determined by quantitative immunoblotting and electrophoresis. Morphometrically were assessed: volume fraction of fibrous tissue; myocyte size, nuclear area, nucleus/sarcoplasm ratio; and nucleus irregularity coefficient. Tissue respiration rate was measured with a Clark electrode in an oxigraphic cell.

RESULTS

The study of the expression of the proteins markers of cardiac hypertrophy showed increased content of tubulin by an average of 42%, desmin by 33% and skeletal myosin beta-isoform by 20%. Expression of protein smooth muscle proteins-markers of embryonic myocytes – alpha-smooth muscle actin and SM22, was increased on average by 1.5 times. In all DCM patients CRP and MLCK levels were increased on average by 52% and 70%, respectively. Thus, in the myocardium of DCM patients a significant part of cardiomyocytes were hypertrophied and there was a partial regression to the fetal protein expression, accompanied by increased expression of CRP and MLCK. The morphometric study showed variable characteristics of cardiomyocytes (tab. I, II).

The alteration in cell characteristics and their area varies broadly in the entire patient series. A few patients presented a characteristic pattern of oversized and bizarre nuclei with markedly high levels of

membrane convolutions. The patients from which these sample were collected formed group I (n = 13), and the remaining patients group II (n = 30). Myocyte size and nuclear area in first group were significantly greater than in group II (tab. III).

TABLE I

Clinical data of the 43 patients with dilated cardiomyopathy

Patients	Sex (M/F)	Mean age (years)	NYHA Class I II III IV	Disease duration (months)
Group I (13)	12 / 1	31 ± 8,4	0 1 6 6	38 ± 21
Age (years)		19 - 46		2 - 144
Group II (30)	25 / 5	36 + 9.0	2 7 13 8	28 ± 24
Age (years)		21 - 56		3 - 120
Total (43)	37 / 6	34 ± 8.6	2 8 19 14	33 ± 22

TABLE II

Histology data from the biopsy samples collected from the 43 patients with dilated cardiomyopathy

	Group I (n=13)%(n)	Group II (n = 30) %(n)	Total (n=43) %(n)
Abnormal nuclei	100/13	0	31/13
Cardiomyocyte hypertrophy:			
mild	15/2	56/17	44/17
moderate	15/2	16/5	16/7
severe	69/9	3/1	23/10
Fibrosis:			
diffuse	38/5	63/19	56/24
focal	31/4	68/18	51/22
Endocardiac changes:			
fibrosis	69/9	80/24	79/34
elastosis	15/2	23/7	21/9
Thrombi	23/3	27/8	25/11
Smooth muscle cells	46/6	27/8	32/14

TABLE III

Morphometric indices, mitochondrial respiratory parameters and hemodynamic data in the DCM patients

Parameters	Group I	Group II
Myofibril diameter (mcm)	30±4*	23±3
Nuclear area (mcm^2)	57±5*	42±6
Nuclear shape index	2.25±0.13*	1.75±0.11
Nucleus/sarcoplasm ratio	0.045±0.004*	0.028±0.003
% - Cr-stimulated respiration	36±4*	90±12
FE VS	0.23±0.03*	0.4±0.08
IVTD VS (ml/m2)	231±59*	121±29
PTD VS (mm Hg)	23±7*	10±4

Also, the nucleus/sarcoplasm ratio and the nuclear shape index were higher in group I. Degenerative alterations of nuclei – breaking of chromatin and lysis of the nucleolema - were observed in 4 group I patients. In 5 patients in the same group, mitochondrial surface area was found to be increased by more than 50% of the myocyte surface area and dominated the myofibrilar surface area, while interstitial fibrosis was similar in both groups.

The electrophoretic analysis of total creatine kinase fraction revealed significant alterations in the expression of creatine kinase isoenzymes. The diseased myocardium had diminished average creatinine kinase content and a higher MB content compared to healthy myocardium (fig. 1).

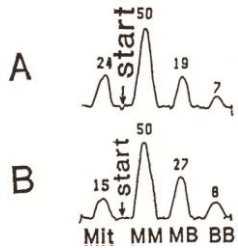

Fig. 1. Spectrum of creatine kinase isoenzyme in normal (A) and dilated (B) human myocardium

This alteration suggests that the insufficient energy transformation due to defective activity of mitochondrial creatine kinase can occur in diseased myocardium. In fact, a very low respiration rate after addition of creatine was found in group I compared to group II (tab. III). There was no significant difference between age-matched groups (tab. I); however, patients in group I had a significantly longer duration of illness and almost all belonged to NYHA classes III-IV. Important differences were noted between groups at cardiac contractile function assessment. The hearts of group I patients showed end diastolic left ventricular pressure (EDLVP) and volume index (VI) significantly higher at the same time with a decrease in ejection fraction (EF) (tab. III). Also, the contractile function parameters and morphometric indices suggestive of cellular hypertrophy correlated with reduced creatine-stimulated respiration.

DISCUSSION

In the present paper, we approached the biochemical aspects of cardiomyocyte hypertrophy in DMC, namely the changes in protein composition of these cells. In mature cardiac tissue, the mechanical load on myocytes causes the release by cardio-myocytes of growth factors and the autocrine stimulation of the expression of a number of genes that initiate thehypertrophic phenotype. Activation of expression of structural and motor proteins is the compensatory response of the cell, which requires strengthening of the cytoskeleton and contractile apparatus. However, an increased synthesis of a series of cytoskeleton proteins may lead over time to pathological changes. Higher level expression of tubulin isoforms, the main constituents of microtubules and intermediate filament protein desmin in animals initially leads to increased stiffness and resistance of microfilaments that bear mechanical load, and is an adaptive process. As these proteins accumulate in the cell, the viscosity of the sarcoplasm that surrounds the functional actomyosin structures increases. As a result, the advancement of myosin filaments relative to actin filament becomes more difficult and contraction efficiency decreases.

Thus, a substantial increase in tubulin and desmin content found by us in our DCM patients can partially influence the maladaptive nature of cardiomyocyte hypertrophy, when, despite the increasing size of functional fibers contraction efficiency is found

to be low. Recently, the presence of marked unusually shaped cardiomyocyte and macronuclei hypertrophy has been reported (7, 8). The authors believe that these changes are characteristic of dilated cardiomyopathy and able to distinguish it from secondary forms. These particular features were used in our research to form a separate study group and to study the particularities of DCM clinical manifestations, depending on the nature and degree of changes in myocardial energy metabolism. We have found that in that group of patients, the relative content of mitochondrial creatine kinase was two times lower, indicating extensive changes in the biosynthesis of various isoferments / isoenzymes in this disease.

With the decrease in mitochondrial creatine kinase the efficacy of phosphocreatine pathway for energy transport decreases considerably, as demonstrated by the sharp drop in creatine-stimulated respiration and aerobic phosphocreatine synthesis in mitochondria. Concomitantly with the reduction of mitochondrial creatine kinase activity in the heart the MB isoenzyme content increases, demonstrating a change of creatine kinase gene expression in the heart with cardiomyopathy. The diminished mitochondrial function of creatine kinase can be explained by the altered expression of the enzyme (9) and sarcoplasmic accumulation of Pi (inorganic phosphate) (10) due to insufficient ATP formation. However, the activity of the enzyme can be associated to the same extent with the low myofibrilar ATPase activity in the diseased heart (10). This supposition is confirmed by the reduction to up to 57% of creatine content in patients with DCM.

Energy transport system disturbances probably lead to a significant increase in diastolic blood pressure and a decrease of ejection fraction. End-diastolic pressure increase in DCM can be largely related to increased myocardial stiffness, due to the increase in myofibrillar ADP as a result of a decreased rate of ADP rephosphorylation because of the diminished efficiency of phosphocreatine pathway for energy transport. As known, ADP is bound to myosin strong enough, with concomitant inhibition of ATPase activity and dissociation of cross-bridges. This may be due to increased end-diastolic pressure and lower ejection fraction in DCM patients presenting the above mentioned features.

CONCLUSIONS

The high myosin light chain kinase and CRP content in the myocardium of patients with DCM demonstrates their involvement in hypertrophy, and can be used in the differential diagnosis of myocardial hypertrophy as a consequence of cardiomyocyte hypertrophy and a result of a predominantly fibrotic process. Energy disorders are significantly more marked in DCM patients in which cardiomyocyte hypertrophy is more pronounced and nuclei are larger in size.

ARM LYMPHEDEMA AFTER AXILLARY DISSECTION

Arm lymphedema is an important complication after surgery intervention for breast cancer. It causes functional and physical defects as well as psychological maladjustments, thereby reducing patient's quality of life. Early diagnosis and treatment is considered important for successful management of breast cancer related arm lymphedema. Patients who have undergone a mastectomy with axillary lymph node dissection have a greater arm-volume and more commonly report symptoms of lymphedema, as compared to patients who have received a sentinel lymph node biopsy. A retrospective review of 57 patients with unilateral arm after an axillary dissection for breast cancer was performed between January 1, 2001 and October 30, 2011. The patients, treated with two weeks of complete decongestive therapy (CDT) and self-administered home therapy, were followed for 24 months. Arm volume was serially measured by using an optoelectronic volumeter prior to and immediately after CDT; and there were follow-up visits at 3, 6, 12, and 24 months. Patients were divided into two groups according to the percent excess volume (PEV) prior to complete decongestive therapy: group 1, PEV<20% and group 2, PEV≥20%. In group 1, mean PEV before CDT was 11.4±5.0% and 14.1±10.6% at 24 months after CDT with no significant difference. At the end of CDT, PEV was 28.8±15.7% in group 2, which was significantly lower than the baseline (41.9±19.6%). The reduction of PEV was maintained for 24 months in group 2. The long-term effects of CDT were well-maintained for 24 months, but there was a difference in progression of PEV between the two groups. The patients with more initial PEV showed significant volume-reducing effects of CDT. In patients with less initial PEV, the severity of lymphedema did not progress to higher grades. (Hwang JM, Hwang JH, Kim TW, et al. Long-term effects of complex decongestive therapy in breast cancer patients with arm lymphedema after axillary dissection. *Ann Rehabil Med. 2013*;37(5):690-677.)

THE INFLUENCE OF ANTIBIOTIC TREATMENT ON THE DYNAMICS OF OXIDATIVE STRESS IN SPONTANEOUS BACTERIAL PERITONITIS (Abstract): Bacterial infections play an important role in liver cirrhosis complications, being together with variceal bleeding and hepatic encephalopathy an important cause of morbidity and mortality in cirrhotic patients. Spontaneous bacterial peritonitis (SBP) is a major complication of liver cirrhosis, with a significant mortality. Recent studies have demonstrated the involvement of oxygen free radicals in the pathogenesis of liver cirrhosis, but the role of oxidative stress in the development of SBP is not very clear yet. **Purpose**: This study aims to evaluate the role of oxidative stress in the pathogenesis of spontaneous bacterial peritonitis and its changes after therapy. **Material and Methods**: The study is a prospective case-control, which included 33 patients divided into 3 groups: group I – 10 patients with decompensated cirrhosis and SBP, group II – 17 patients diagnosed with decompensated liver cirrhosis with ascites, and group III – 6 patients with compensated liver cirrhosis. The control group consisted of 19 healthy subjects recruited from hospital staff, adapted to patients by age and sex. Malonildyaldehida (MDA), a product of lipid peroxidation, was dosed in the blood and ascitic fluid of patients by assay thiobarbituric acid reactive substances (TBARS). **Results**: Serum MDA significantly increased in the group with decompensated cirrhosis and SBP compared with the control group. MDA levels in ascitic fluid showed a statistically significant increase in the SBP group compared with patients without SBP. There was a decrease of MDA after 6 months of antibiotic treatment compared with the initial stage, while MDA values increased in the absence of treatment. **Conclusions**: The study demonstrates the increased oxidative stress markers in the blood and ascitic fluid of cirrhotic patients with SBP, which can be considered a predictor of SBP and also a marker of treatment response. **Keywords**: SPONTANEOUS BACTERIAL PERITONITIS, OXIDATIVE STRESS, ANTIBIOTIC TREATMENT, PROPHYLAXIS.

Bacterial infections play an important role in liver cirrhosis complications, being together with variceal bleeding and hepatic encephalopathy an important cause of morbidity and mortality in cirrhotic patients (1). Compared with the general population, the incidence of infections such as peritonitis, pneumonia, urinary tract infections or meningitis is 10 times higher in cirrhotic patients and the mortality is 20 times high-

er, pointing out that liver cirrhosis is a status of acquired immune deficiency (2).

Spontaneous bacterial peritonitis (SBP) is a major complication of liver cirrhosis, with a significant mortality. The incidence of SBP in hospitalized patients with cirrhosis is between 7% and 23%. The probability for a patient with cirrhotic ascites to develop the first episode of SBP is 10% per year, but it increases in ascites with low protein concentration (below 1g / 100ml) and severe hepatic impairment (1, 2).

In most cases, SBP is a monobacterial infection of the ascitic fluid; its culture reveals a single microorganism, the number of neutrophils being over 250/mmc.

SBP probably develops as a consequence of ineffective defense mechanisms against infection, seen in patients with liver cirrhosis. Although the key steps in the pathogenesis of SBP are not fully elucidated, it is clear that the main source of infection is the bacterial gut, while the altered intestinal motility promotes the bacterial translocation, a key element in the pathogenesis of SBP (3).

Despite all protrective measures, such as early diagnosis and prophylactic antibiotic therapy, as well as the introduction of new antibiotics, albumin infusions, the prognosis of these patients remains poor, with a mortality rate of 20-40% (4). The installation of an episode of spontaneous bacterial peritonitis reduces the survival rate to about 30% per year and 20% at 2 years.

The literature shows a mortality rate of 50% during hospitalization; 70% of SBP relapse, and 80% of patients die within the first year after the initial infectious episode (5). In this context, the identification of patients with increased risk of death is extremely important for improving their prognosis.

Early establishment of an appropriate antibiotic therapy is critical in most cases of SBP.

Knowing the risk factors for SBP is important not only in order to identify patients who could benefit from the preventive therapy, but also in understanding the pathogenesis of the disease.

Identifying risk factors for SBP is important in the development of a safe and cost-effective prophylactic strategy.

A new concept much-discussed lately is oxidative stress. It is defined as the imbalance between oxidants and antioxidants in the favor of oxidants, with destructive and pathogenic potential. The oxidants are normally formed during aerobic metabolism and their amount increases under certain conditions. In such circumstances, physiological antioxidant mechanisms that inactivate reactive oxygen species and repair several molecular lesions may prove insufficient. The imbalance between the oxidant and antioxidant capacity of the body is called oxidative stress and is the origin of various diseases with a high prevalence in modern medicine, such as proliferative diseases, atherosclerosis, glomerulonephritis, pulmonary fibrosis and cirrhosis (6).

Recent studies have demonstrated the involvement of oxygen free radicals in the pathogenesis of liver cirrhosis, but the role of oxidative stress in the development of SBP is not very clear yet. However, recent studies have shown the important role of oxidative stress in increased intestinal permeability, an important element in the pathogenesis of SBP. In patients with liver cirrhosis there is an intestinal motility disorder, which promotes intestinal bacterial overpopulation. Bacterial translocation is possible due to intestinal barrier alteration. In the experimental conditions of lipid

peroxidation, infiltrations with neutrophils were observed in the intestinal mucosa, lesions which are correlated with bacterial translocation and portal hypertension, major factors in the development of SBP (7).

The free radicals, also called pro-oxidants, are compounds of circulating blood, very active, biochemically and biologically virulent, acting on membranes, nuclei and cell cytoplasm, producing and maintaining an intense oxidative stress (8). Antioxidant defense is achieved by the endogenous antioxidants and, where these systems are overcome, by means of the exogenous antioxidants. Antioxidants are designed to neutralize or remove reactive oxygen and nitrogen species and products of lipid peroxidation. It is always desirable that the level of pro-oxidants (free radicals) should be below the capacity of the antioxidants. When free radicals exceed the antioxidants (oxidative stress), phenomena of wear and early cellular aging appear (9).

Early establishment of an appropriate antibiotic therapy is critical in most cases of SBP. Empirical antibiotic treatment should be initiated prior to receiving the result of ascitic fluid cultures and blood cultures if the clinical picture is pathognomonic and the PMN number is above 250/mmc. The results of the cultures allow subsequent adaptation of the treatment regimen (10).

For over two decades, third generation cephalosporins were the antibiotics of choice in the treatment of SBP. Felisart et al. in 1985 have validated the use of cefotaxime as an empiric antibiotic choice in the treatment of SBP, further studies determining the optimal dose and duration of therapy. A recent study by Navas et al. demonstrated that oral therapy with ofloxacin is as effective as that with cefotaxime iv in patients with uncomplicated SBP (11).

Prophylactic antibiotic treatment aims to selective decontaminate the gastro-intestinal tract in order to reduce the risk of developing spontaneous bacterial peritonitis. Given the increased cost and risk of developing resistant organisms, antibiotic prophylaxis is indicated in three cirrhotic groups: those with a history of SBP, those hospitalized for upper gastrointestinal bleeding, those with low-protein ascitic fluid.

MATERIAL AND METHODS

The study is a prospective case-control, which included 33 patients divided into 3 groups: group I – 10 patients with decompensated cirrhosis and SBP, group II – 17 patients diagnosed with decompensated liver cirrhosis with ascites, and group III – 6 patients with compensated liver cirrhosis. The control group consisted of 19 healthy subjects recruited from hospital staff, adapted to patients by age and sex. Malonildyaldehida (MDA), a product of lipid peroxidation, was dosed in the blood and ascitic fluid of patients by assay thiobarbituric acid reactive substances (TBARS). MDA levels were statistically analyzed using one-way analysis of variance (ANOVA). The results are expressed as mean ± SEM. The values of F for which $p < 0.05$ were considered statistically significant.

RESULTS

Serum MDA levels, a marker of lipid peroxidation, have experienced significant growth both in the group with decompensated cirrhosis and SBP ($F(1.24) = 53$, $p = 0.0000001$) and in the group with decompensated cirrhosis without SBP ($F(1.31) = 30$, $p = 0.000005$) in comparison with the control group (fig. 1).

Regarding MDA levels in ascitic fluid,

there was also a statistically significant MDA increase in the group with SBP compared with patients without SBP (F (1.20) = 5, p = 0.047) (fig. 2).

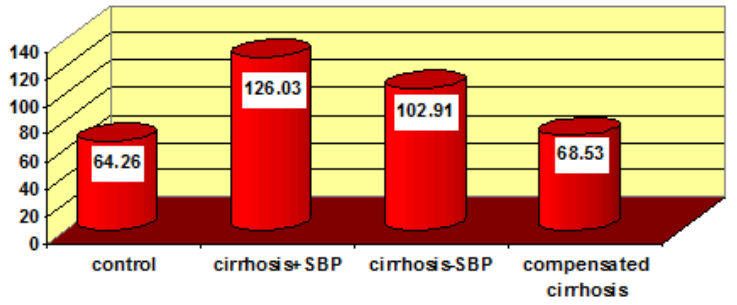

Fig. 1. MDA levels in serum in our research groups

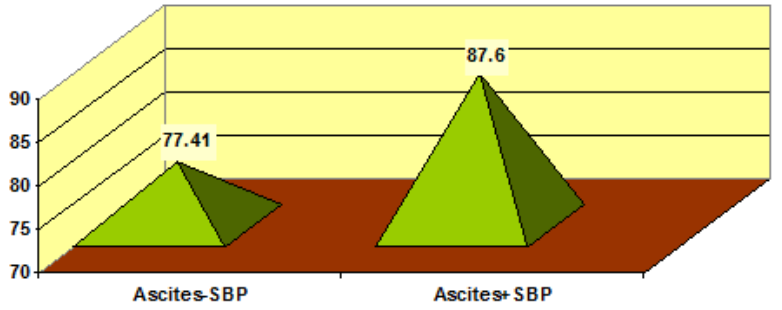

Fig. 2. MDA levels in ascitic fluid in our research groups

Regarding the evolution of MDA in the context of prophylactic antibiotic treatment, there was a decrease in MDA after 6 months of antibiotic treatment compared to the initial stage, whereas MDA values increased in the absence of treatment (fig. 3).

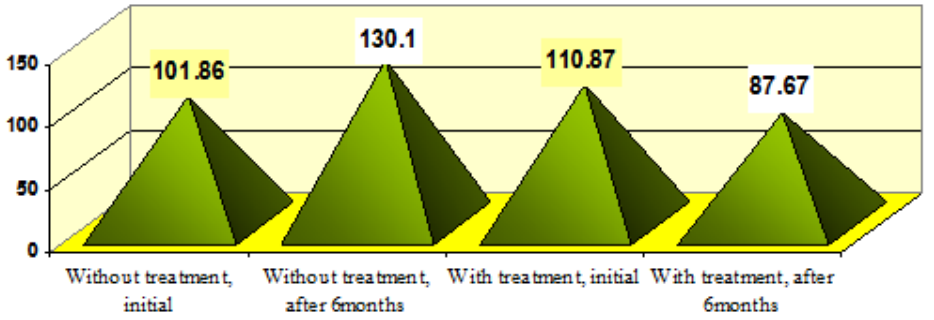

Fig. 3. The evolution of MDA in patients with and without treatment

TABLE I

Average values of oxidative stress markers in patients with and without treatment, initially and after 6 months

Oxidativ stress marker	Without treatment (3 cases)				With treatment (6 cases)			
	Before		After		Before		After	
	Average	Ab. st.	Average	Ab. St.	Average	Ab. st.	Average	Ab. st.
MDA	101.86	18.383	130.10	24.673	110.87	19.351	87.67	19.989

DISCUSSION

The results obtained showed the presence of oxidative stress, increased markers of lipid peroxidation, suggesting the involvement of oxidative stress in SBP and its dynamics within the context of antibiotic therapy.

A recent study by S Bhandari et al. demonstrated the role of oxidative stress in worsening the severity of cirrhosis, assessed by Child-Pugh score, by determining the levels of pro-oxidant substances (serum levels of MDA) and of the antioxidant (superoxide dismutase and glutathione peroxidase) in cirrhotic patients (12).

Previous studies on rats with experimental model of liver cirrhosis induced by alcohol and iron found elevated levels of MDA in the liver. A significant increase in plasma MDA levels was also observed (13).

A recent study published by Shaden M et al., demonstrated the involvement of oxidative stress in SBP (14). Oxidative stress was evidenced by elevated MDA and by significantly reduced antioxidant components SOD, GPx. After antibiotic treatment, MDA, NO and TNF expression significantly decreased and there was significant increase in antioxidant elements. Also, in a study by Natarajan SK (15), a significant increase of ascitic MDA was observed in patients with SBP compared to controls. This study demonstrated the presence of oxidative stress in the ascitic fluid from patients with SBP and showed that the nitrate in the ascitic fluid may be a marker for diagnosis of SBP and an useful index to determine the therapeutic response to treatment with antibiotics.

Understanding this is important because the interaction between NO and superoxide may cause extremely damaging reactive species, such as Peroxynitrite.

Randomized trials have demonstrated the efficacy of intravenous cefotaxime, which is the antibiotic of choice in SBP (16).

In determining the therapeutic response in patients with SBP, Natarajan et al. measured the parameters of oxidative stress in relation to the number of neutrophils in the ascitic fluid. The study showed a decrease of NO in the ascitic fluid, in concordance with the number of neutrophils. Park et al demonstrated no significant change in nitrate from ascites of patients with SBP after treatment with antibiotics. However, the nitrate levels in ascites per se were altered in patients with SBP in this study, in contrast to data from other studies (17).

A Geetha et al. (12) demonstrated that in cirrhosis red cells undergo severe oxidative stress with significant changes in membrane properties. Oxyhemoglobin and methemoglobin levels were analyzed in blood red cells. Markers of oxidative stress, such as lipid peroxides, lipid hydroperoxides, as well as nitric oxide, were deter-

mined with enzymatic anti-oxidants. Methemoglobin level was significantly higher ($p < 0.001$) in erythrocytes of patients with liver cirrhosis complicated with bleeding compared to patients without bleeding. Levels of oxidative stress markers, including nitric oxide has been shown to be higher in these patients.

Enzymatic antioxidants levels were low. Gines, in his study, showed that norfloxacin, a selective quinolone for gram-negative bacilli with low absorption in dose of 400mg/day reduces the risk of SBP recurrence in the first year from 68% to 20% (18).

Five randomized trials have shown the net benefit of using short-term antibiotic prophylaxis in cirrhotic patients admitted with variceal bleeding. A meta-analysis showed a significant decrease in the rate of infection in patients receiving antibiotic treatment on admission (19).

Grange et al. (20), in a randomized placebo-controlled trial evaluating norfloxacin as primary prophylaxis in cirrhotic patients with low ascitic fluid protein, demonstrated a decreased incidence of SBP in the group that received antibiotics (2%) compared with the placebo group (17%) and also decreased mortality rates at 6 months (19% vs. 36%).

CONCLUSIONS

Our results demonstrate the presence of increased oxidative stress in patients with decompensated cirrhosis and SBP, compared to those without SBP and those with compensated liver cirrhosis. This was shown by increased MDA, a marker of lipid peroxidation.

Thus, measurement of this parameter of oxidative stress may play an important role in the diagnosis and follow up of this important liver pathology

PHARMACOLOGICAL ACTIVITY OF MYRTUS NIVELLEI ESSENTIAL OIL

Sahara myrtle is a medicinal plant traditionally used for dermatosis treatment. In order to justify the use of this plant, Bouzabata *et al.* aimed to elucidate the composition of *Myrtus nivellei* essential oil extracted by hydrodistillation of aerial parts, its antifungal properties and the cytotoxicity on keratinocytes. Chemical analysis using chromatographic and spectroscopic techniques elucidated the structure of two new compounds and showed a different composition of *Myrtus nivellei* oil from that of *Myrtus communis*. Broth macrodilution method was used to evaluate the activity against yeasts and filamentous fungi. Determination of MICs showed that the oil was more active against *Cryptococcus neoformans* (MIC = 0.16µL/mL), followed by dermatophytes (MICs of 0.64 and 1.25µL/mL). Evaluation of cell viability in HaCaT keratinocytes revealed no cytotoxicity at concentrations up to 1.25µL/mL. Thus, appropriate doses of *Myrtus nivellei* oil could be found, having antifungal activity and very low cytotoxicity on keratinocytes. (Bouzabata A, Bazzali O, Cabral C, Gonçalves MJ, Cruz MT, Bighelli A, *et al*. New compounds, chemical composition, antifungal activity and cytotoxicity of the essential oil from Myrtus nivellei Batt. & Trab., an endemic species of Central Sahara. *J Ethnopharmacol.* 2013 Jul 31. pii: S0378-8741(13)00487-X. doi: 10.1016/j.jep.2013.06.054.)

ZENKER'S DIVERTICULUM, A RARE CAUSE OF UPPER GASTROINTESTINAL BLEEDING

C. Bălălău[1], S. Stoian[1], I. Motofei[1], B. Popescu[2], F. Popa[1], R.V. Scăunaşu[2]

ZENKER'S DIVERTICULUM, A RARE CAUSE OF UPPER GASTROINTESTINAL BLEEDING (Abstract): The most common complication of Zenker's diverticulum is aspiration pneumonia, compression of the trachea and esophageal obstruction with large diverticulum, and increased risk of development of carcinoma. Thus bleeding occurs rarely, can be massive and life threatening, with ulceration being the most common cause. **Material and methods:** We describe a patient with sever upper gastrointestinal bleeding as a result of a Zenker's diverticulum. A 75 year-old woman was referred to the emergency room and hospitalized for hematemesis, melena, asthenia and total dysphagia. In this particular case we preferred open technique because of the diverticulum dimensions and bleeding episode. Left cervicotomy was practiced on the anterior edge of the sternocleidomastoid muscle, being known that Zenker diverticulum extend into the left neck 90% of the time, fact also confirmed by radiology in this case. **Results:** Postoperatively, the patient showed a complication free recovery. Five days after treatment the patient resumed nourishment. Several days later our patient was able to return home. Follow-up at 12 months after the operation showed complete recovery. Ulcer of the basis of Zenker's diverticulum is a rare entity and, only a few cases were reported in the literature to date. Omitting thecricomyotomy predisposes to fistula or diverticulum recurrence due to the persistence of a high pharyngeal intraluminal pressure that acts on the posterior wall just proximal to the upper esophageal sphincter. **Conclusions:**Zenker's diverticulum is an unusual site of origin for clinically significant upper gastrointestinal hemorrhage and differential diagnosis must include other more frequent causes of upper gastrointestinal bleeding. In our opinion, classicalsurgical therapy is indicated when distal esophageal imaging cannot be obtained during endoscopic examination, there is a large diverticulum or in an emergency setting when fast control over the bleeding source is required. **Keywords:** ZENKER'S DIVERTICULUM, GASTROINTESTINAL BLEEDING, CERVICOTOMY

Zenker's diverticulum is a pulsion-type diverticulum of the hypo pharynx, the result of herniation of the esophageal mucosa and submucosa through the area of natural weakness known as Killian's triangle.

It is hypothesized that abnormal activity in the cricopharyngeus muscle results in an uncoordinated swallowing mechanism, which, coupled with increased intraluminal pressure, results in the slow, progressive distention and herniation of the pharynx mucosa (1). The incidence of Zenker's Diverticulum is estimated at 2 per 100,000, with highest prevalence rates in the 7th and

8th decades of life. Risk factors for development of Zenker'sdiverticulum include presence of hiatal hernia and/or gastro esophageal reflux disorder (GERD), male gender and age (1, 2).

The most common complication of Zenker's diverticulum is aspiration pneumonia, compression of the trachea and esophageal obstruction with large diverticulum, and increased risk of development of carcinoma (3). Thus bleeding occurs rarely, can be massive and life threatening, with ulceration being the most common cause.

Since its description by Zenker and von Ziemssen in 1877, numerous surgical techniques have been developed to treat the diverticulum. Initially, transcervical resection of the diverticular pouch has been the procedure of choice (4). However, the diverticular sac is in fact a consequence of the high pharyngeal pressure secondary to a lack of compliance of the cricopharyngeus muscle in relation to local fibrosis. Consequently, due to unacceptably high rate of recurrence, cricopharyngeal myotomy (CPM) was recommended for the management of the physiologic abnormality (5, 6).

Endoscopic therapy can be applied in two forms, either by the application of diathermic or laser coagulation, or stapling technique, which allowed an endoscopic suture of the cut margins (7, 8, 9, 10) (tab. I).

Size of the diverticulum determines which procedure to carry out (11, 12) (tab. II).

TABLE I

Endoscopic and open techniques

Endoscopic techniques	Open techniques
Endoscopic stapled diverticulostomy	CPM
CO_2 laser / Electrocautery	CPM with diverticulectomy
	CPM with diverticulopexy

TABLE II

Criteria of the Morton and Bartley

Criteria	Surgical technique
I. Small sacs are less than 2 cm in length	CP myotomy alone is sufficient
II. Intermediate sacs are 2-4 cm in length	Endoscopic or open procedure can be used
III. Large sacs are greater than 4 cm in length	Open surgery

We describe a patient with sever upper gastrointestinal bleeding as a result of a Zenker's diverticulum. A 75 year-old woman was referred to the emergency room and hospitalized for hematemesis, melena, asthenia and total dysphagia. She was known to have endured various respiratory tract infections in the previous several months and had difficulty to swallow solid foods for a few months. During the previous few days the ingestion of fluids had become impossible.

The clinical exam reveals pallor, evidence of dehydration and a 5 by 3 cm palpable tumor on the left side of the neck. Patient was tachycardic but with normal blood pressure. Blood exams shows moderate anemia. Esophagography with barium revealed a medium to voluminous pharyngo-esophageal diverticulum.

Surgical treatment was decided. In this particular case we preferred open technique because of the diverticulum dimensions and bleeding episode. Left cervicotomy was practiced on the anterior edge of the sternocleidomastoid muscle, being known that Zenker diverticulum extend into the left neck 90% of the time, fact also confirmed by radiology in this case.

The omohyoid muscle was cleaved and the superior thyroidian artery and vein were ligated and cleaved, in order to obtain suitable diverticulum exposure. The recurrent laryngeal nerve was identified and protected.

The diverticulum, with a diameter of approximately 3-4 cm, is identified and dissected (fig. 1). A Faucher probe was passed with some difficulty into the distal esophagus. Esophageal and crico-pharyngeus muscles are longitudinally divided for 3-4 cm. Mechanical suture at the base of the diverticulum is practices with aid of a TA 30/3.5 stapler (fig. 2). The diverticulum is sectioned close to the stapler (fig. 3).

Fig. 1. The diverticulum, identified and dissected

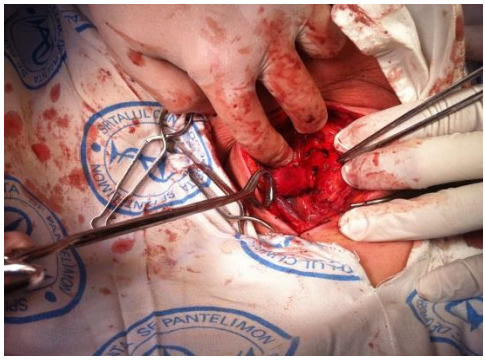

Fig. 2. Mechanical suture at the base of the diverticulum

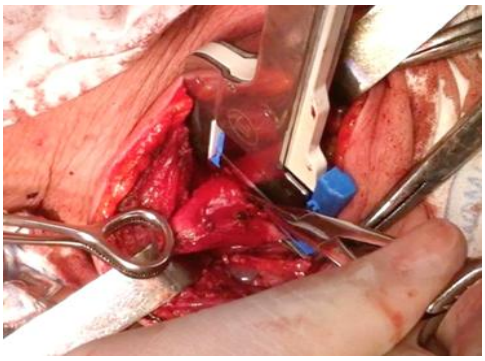

Fig. 3 The diverticulum is sectioned close to the stapler

Final aspect after removing stapler and control of suture sealing and hemostasis (fig. 4). The excised diverticulum containing traces of barium from previous examination (fig. 5). Paraesophageal drainage through counter incision was preferred ostoperatively, the patient showed a complication free recovery. Five days after

treatment the patient resumed nourishment. Several days later our patient was able to return home. Follow-up at 12 months after the operation showed complete recovery.

Fig. 4. Final aspect after removing stapler

Fig. 5. The excised diverticulum

DISCUSSION AND CONCLUSIONS

As a summary, the case is rare complication of Zenker's diverticulum that was initially misdiagnosed as having esophageal varices. Ulcer of the basis of Zenker's diverticulum is a rare entity and, only a few cases were reported in the literature to date (1, 5, 6). The diverticulum had a deep ulceration that was the source of the bleeding. The cause of the ulceration is unknown but it is possible that the ulcer has been caused by chronic NSAID or other ulcerogenicdrugs prescribed for prior respiratory infections. Chronic alcohol abuse was the other contributing factor, known to predispose ulcer formation by facilitating the development of gastroesophageal reflux and stimulation of acid secretion (7, 8, 9).

Zenker's diverticulum is an unusual site of origin for clinically significant upper gastrointestinal hemorrhage and differential diagnosis must include other more frequent causes of upper gastrointestinal bleeding (10, 11).

In our opinion, classical surgical therapy is indicated when distal esophageal imaging cannot be obtained during endoscopic examination, there is a large diverticulum or in an emergency setting when fast control over the bleeding source is required.

Omitting thecricomyotomy predisposes to fistula or diverticulum recurrence due to the persistence of a high pharyngeal intraluminal pressure that acts on the posterior wall just proximal to the upper esophageal sphincter (12, 13).

MALIGNANT MESOTHELIOMA: NONASBESTOS-RELATED ASSOCIATIONS

It should be realized that although there is a strong link between the development of malignant mesothelioma (MM) and asbestos exposure, not all cases are etiologically related to asbestos exposure. The proportion of cases attributable to asbestos exposure varies between the sexes and country, according to occupation and use of amphibole asbestos. A number of other agents have been implicated in the causation of MM but the best evidence appears to relate to another mineral fiber (erionite) and to irradiation. However, there is strong experimental, epidemiologic and molecular evidence to suggest a possible carcinogenic or cocarcinogenic role of viruses such as simian virus 40 (SV40), a monkey polyoma virus, in the induction of MM. Malignant mesothelioma has followed 20 years after plombage therapy with lucite spheres for tuberculosis. Additional cases have been associated with chronic empyema, chronic peritonitis, induced pneumothroax for tuberculosis, and familial Mediterranean fever. (Jasani B, Gibbs A. Mesothelioma not associated with asbestos exposure. *Arch Pathol Lab Med*. 2012;136:262–267).

STABILITY AND CHANGE IN THE CLINICAL COURSE OF SCHIZOAFFECTIVE DISORDER (Abstract): Schizoaffective disorder currently raises several questions, one of them being related to the stability of the clinical diagnosis over time. The **aim** of this study is to identify the clinical and evolutional particularities in the longitudinal course of schizoaffective disorder. **Material and methods:** 44 subjects with a current diagnosis of schizoaffective disorder have been assessed prospectively. Following parameters were analyzed: socio-demographic (age at onset, gender, educational, professional and marital status at onset) and clinical (total duration of evolution, diagnosis at onset, duration of the evolution until the switch to the schizoaffective disorder diagnosis). **Results and discussion:** Socio-demographic parameters are similar to those in literature and the clinical assessment revealed that schizoaffective disorder is present as a diagnosis along with the longitudinal course of other types of psychosis. **Conclusions:** Schizoaffective disorder appears as a heterogeneous pathology in terms of the longitudinal course. **Keywords:** SCHIZOAFFECTIVE DISORDER, DIAGNOSIS STABILITY, LONGITUDINAL COURSE.

We have addressed in this study one of the controversial topics of today's psychiatry, namely the concept of schizoaffective disorder (1). Generally, current concerns that regard schizoaffective disorder are linked to the question whether schizoaffective disorder is a nosological entity distinct from schizophrenia or from affective disorders? From a clinical point of view, another question is related to the stability of the diagnosis of schizoaffective disorder in terms of its clinical longitudinal course.

The circumscription of schizoaffective disorder varies in scientific literature between the following guidelines: schizoaffective disorder with only schizoaffective episodes , schizoaffective disorder that also presents along with its course schizophrenia episodes, purely delusional episodes or even a combination of both, schizoaffective disorder that has mainly schizophrenia episodes to which schizoaffective episodes are added and schizoaffective disorder that has mainly affective episodes to which schizoaffective episodes are added. Generally, the interferences between schizophrenia, schizoaffective disorder and affective disorders can widely vary and their clarifi-

cation can be achieved through longitudinal studies. The results of these studies are controversial, varying from results that show that there are differences between these disorders to the ones that show no differences.

The aim of this study is to identify clinical and evolutional particularities in the longitudinal course of schizoaffective disorder. One of the specific features of this study is the minimum of 15 years of psychotic pathology evolution of the subjects accepted in this research.

MATERIAL AND METHODS

The research was conducted on a total of 44 subjects who were admitted for the first time in Timisoara Psychiatric Clinic between 1985 and 1995. These subjects have been diagnosed during their first admission with a first episode of psychosis and currently, in the year 2011, have a schizoaffective disorder diagnosis. Since we have considered a clinical population, the sample does not claim to be statistically representative and we have not used random or quota sampling techniques, but we have applied inclusion/exclusion criteria.

Inclusion criteria: diagnosis of schizoaffective disorder (F25 according to the ICD-10 criteria) at the assessment, meaning the current diagnosis , at least 15 years of evolution of the pathology from the first episode of psychosis, age under 60 years at assessment, subjects who are able and willing to cooperate with the assessor - we have obtained the informed consent of the subjects that have participated in this study and outpatients of Timisoara Mental Health Centre and of the ambulatory psychiatric surgeries from Timisoara. *Exclusion criteria*: the presence of other associated psychiatric disorders: mental retardation, alcoholism, personality disorders. We mention that where necessary we have used the conversion tables of ICD 9/ICD 10, because the onset diagnosis was made according to ICD 9.

The study sample has been assessed based on the data from the existent research project of Timisoara Psychiatric Clinic, through direct discussions with the subjects but also with the physicians who are regularly seeing the patients in ambulatory. Following parameters were analyzed: social and demographic (age at onset, gender, educational status at onset, professional and marital status at onset) and clinical and evolutionary (total duration of evolution, diagnosis at onset, and duration of the evolution until the switch to the schizoaffective disorder diagnosis).

RESULTS

For the subjects included in the study the overall average evolution is of 21.5 years (std. dev. 3.67 years), with a minimum of 15 years of evolution and a maximum of 30 years.

The diagnostic assessment from the onset was performed using the existing records from our clinic and also with the help of the conversion tables from ICD-9 to ICD-10 diagnosis (fig. 1).

Since it is of great interest to determine the average time required for the stabilization of the symptoms and for the framing of the disease into the nosological category of schizoaffective disorder, we took into account the period of time (in years) for the subjects we have investigated, from the onset to the establishment of the schizoaffective disorder diagnosis. Therefore, for establishing the diagnosis of schizoaffective disorder for the subjects included in the study sample 5.98 years (std. dev. 3.23)

were needed, with a minimum of 1 year and maximum of 14 years. The average length of time for the change of the diagnosis varies according to the diagnosis at onset (fig. 2).

TABLE I

Socio-demographic characteristics of the sample

Socio-demographic characteristics	Schizoaffective disorder sample (N=44)
Average age at onset	25.45 (std.dev. 6.17 years)
Gender:	
male	18
female	26
Educational status :	
10 grades	3
High school	41
Average years of school	11.7
Professional status :	
Employed	32
Unemployed	2
High school/college student	10
Marital status:	
Married	17
Single	21
Divorced	6

TABLE II

The distribution on groups of years of evolution

Evolution years at assessment	Schizoaffective disorder sample			
	Number	Cum.number	Percentage	Cum.percentage
15-19 years	15	15	34,09091	34,0909
20-24 years	23	38	52,27273	86,3636
25-30 years	6	44	13,63637	100,0000

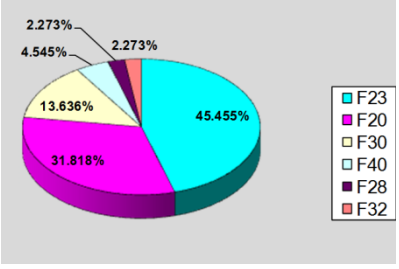

Fig. 1. Distribution of the sample according to the diagnosis at onset

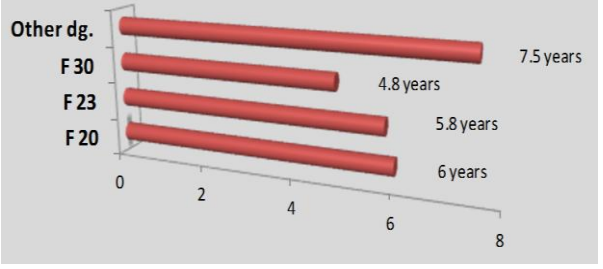

Fig. 2. The diagnosis at onset / the average of time for the change of the diagnosis

DISCUSSION

Generally, the assessment of the socio-demographic parameters is similar to that illustrated in the scientific literature (2). The average age at onset is one that corresponds to the young adult period and the gender distribution shows that schizoaffective disorder prevails among female, this is also shown in the majority of the studies (3, 4). To note that the study we conducted has no epidemiological value since we have not used any statistical methodology for the inclusion of the subjects in the sample. The average length of schooling is about the same having a value of 11 years which corresponds to a medium tuition. From the point of view of the profession we observe that most subjects are performing an activity (72.7%), whether they were or they are enrolled in schools (20.4%). Family status shows that most are unmarried (47%) - a predictable percentage since their young age at onset.

The evolution course is very long when comparing with most clinical research. It can be observed that most subjects (n=23) have an evolution of 20 to 24 years. Regarding the diagnosis of onset we notice that no subjects had a schizoaffective disorder diagnosis - this diagnosis has been placed somewhere along the course of the disease. The diagnoses palette is diversified, but with the observation that a large number of subjects has a diagnosis of acute and transient psychotic disorder (45.5%), followed by schizophrenia (31.8%). There were also a reduced number of subjects included who experienced at onset an affective pathology (manic or depressive).The average length of time necessary for the change of the diagnosis varies depending on the diagnosis at onset, the shortest being for the subjects who had an affective pathology at onset (4.8 years) and the longest for those with a diagnosis of schizophrenia (6 years). In this research we have also included subjects who had at onset a diagnosis of other psychotic disorders (according to ICD 10) or even of neurosis. For this subgroup the time until the change of the diagnosis was higher (7.5 years). This is however correlated with the diversity of the clinical diagnoses.

Schizoaffective disorder is a nosological category for which establishing a diagnosis from onset is rarely possible, more often it is only possible to identify psychotic features and a great variability of psychotic symptoms. The establishment of the diagnosis of schizoaffective disorder is to be made after a period of evolution of the pathology (5).

CONCLUSIONS

Schizoaffective disorder appears as a heterogeneous pathology in terms of longitudinal course, meaning that most cases that reach this diagnosis also have other diagnoses during their evolution, especially in the period that follows the onset. From the clinical point of view it is important to distinguish between schizoaffective disorder and schizoaffective episode, nuance which is not currently achieved by the diagnostic systems.

NEW INSIGHT INTO MOLECULAR EPIDEMIOLOGY OF MRSA STRAINS IN ROMANIA

A recent study by Székely and co. brings new informations regarding methicillin-resistant *Staphylococcus aureus* strains (MRSA) circulating in Romania. The authors used pulsed-field gel electrophoresis (PFGE), *spa* typing and SCC*mec* typing to describe the clonal relations and virulence profiles of MRSA isolates from patients admitted to intensive care and surgical units, during 2010, in Mures County Emergency Clinical Hospital. The study identified 25 pulsotypes clustering into 4 major clonal groups, named from A to D. The majority of MRSA isolates, included into clonal group A (82%), were associated with the successful HA-MRSA clone, spa type t030, which carried SCC*mec* type III and enterotoxin A genes. Group B was represented by 15 % of the strains, which were assigned to spa types t127, t015 and t321. These strains harboured SCC*mec* type IV and enterotoxin genes. Two strains that belonged to spa types t044 and t582 were included into clonal groups C and D, respectively. They were PVL-producing strains (Panton-Valentine leukocidin) and had genes encoding for enterotoxin G and SST-1 (toxic shock syndrome toxin). The remaining two strains were non-typeable by PFGE and belonged to spa type t034, which is characteristic for livestock-associated MRSA (LA-MRSA). These strains were isolated from community onset infections, harboured SCC*mec* type V and were negative for the searched exotoxins. The study concluded that most MRSA strains were clonally related and suggested an intrahospital origin, but also pointed out the danger of new emerging LA-MRSA strains. (Székely E, Man A, Mare A, Vas KE, Molnár S, Bilca D, *et al*. Molecular epidemiology and virulence factors of methicillin-resistant *Staphylococcus aureus* strains in a Romanian university hospital. *Rev Rom Med Lab*. 2012; 20: 370-382).

2. Discipline of Endocrinology

RELATIONSHIP BETWEEN BONE MINERAL DENSITY, WEIGHT, AND ESTROGEN LEVELS IN PRE AND POSTMENOPAUSAL WOMEN **(**Abstract): Bone loss in postmenopausal women is mainly due to estrogen deficiency affecting the balance between osteoclast resorption and bone formation controlled by osteoblasts. **Aim:** To determine the relationship between bone mineral density (BMD) in pre and postmenopausal Caucasian women, and estrogen levels. **Material and methods:** Cross-sectional study including six groups of 8 to 15 pre- and postmenopausal healthy volunteers with different weights, body mass index (BMI) (normal or underweight < 25 kg/m^2, overweight 25-30 kg/m^2, and obese > 30 kg/m^2), not exposed to antiosteoporotic therapy. Lumbar bone mineral density (BMD) and body composition (BC) were evaluated by dual X ray absorptiometry (DXA, Hologic), while serum estradiol and estrone were measured by ELISA. **Results**: BMD in postmenopausal women is lower than in premenopausal women irrespective of body weight ($p<0.05$). Estradiol and estrone are positively correlate with bone mass in premenopausal women, but not in postmenopausal women (R2 0.3209, R2 0.2579, respectively). **Conclusions**: It is very important to identify the risk factors for osteoporosis, especially in postmenopausal women, as we will show that aromatization of androgens into estrogens in adipose tissue appears not to have a significant role in postmenopausal women bone protection. **Keywords**: BODY COMPOSITION, MENOPAUSE, ESTRONE, ESTRADIOL.

Osteoporosis is a chronic disease of the skeletal system characterized by a decrease in bone mass and abnormalities of bone tissue microarchitecture resulting in bone fragility and risk for fracture. It is a public health issue, solely in Romania being approximately 1.5 million patients with osteoporosis, hence the interest in better understanding the factors that determine the occurrence of osteoporosis (1, 2).

MATERIAL AND METHODS

Cross-sectional study on 6 groups of about 8 women each. Age dstribution: 31 premenopausal women and 37 postmenopausal (at least two years of menopause). BMI: normal and underweight (BMI <25 kg/m^2), overweight (BMI between 25-30 kg/m^2) and obese (BMI> 30-40 kg/m^2). Age-group and BMI distribution: premenopausal women: 16 normal and underweight, 9 overweight, and 6 obese; postmenopausal women: 8 normal and underweight, 11 overweight, and 17 obese. All women volunteered to participate in this study, and were recuited into

the study from patients, students and staff of Iasi „St. Spiridon" County Emergency Hospital. A signed informed consent was obtained from all women.

Exclusion criteria were: diabetes mellitus, osteoporosis under treatment, hormone replacement therapy, severe liver or kidney disease, hyperthyroidism, primary hyperparathyroidism, hypo-gonadism, growth hormone deficiency, Cushing's syndrome, corticotherapy for over a year, anorexia nervosa, malabsorption syndrome, genetic syndromes. A fasting blood sample was collected, centrifuged, and stored in a refrigerator (-30°C) for estrone and estradiol determinations. Then, for all volunteers height and weight were measured, and subjected to osteo-densitometry by dual X-ray absorptiometry (DXA). A certified technician measured bone mineral density (BMD) of the lumbar spine on Hologic DXA. Total fat and lean masses were expressed in grams. Lumbar BMD was expressed in g/cm^2. Leptin (ng / ml), adiponectin (mg / l), IGF-1 (µg / l) were determined using commercial ELISA kits (Diagnostic Automation Inc., Calabasas, CA) The results were statistically processed using NCSS 2007 software, simple Pearson correlation, student t test, the correlation being considered significant when $p < 0.05$. Multivariate regression (ANOVA) was used to exclude systematic biases.

RESULTS

Bone mineral density was significantly lower in postmenopausal compared with premenopausal women ($p < 0.05$) (fig. 1).

The relation between various body compartments and total body bone mass was followed in all volunteers. BMI positively correlated with lumbar BMD, T score, and Z score. The best correlation was with Z score, because this parameter excludes age-related influence on bone (fig. 2).

Given the heterogeneity of the study group we used Z score, which compares BMD with age-matched mean BMD.

Body compartments correlate differently to lumbar Z score. Thus, in our study series Z score was correlated with total body weight expressed as BMI, the correlation being positive and significant in both pre- and postmenopausal women. (fig. 3).

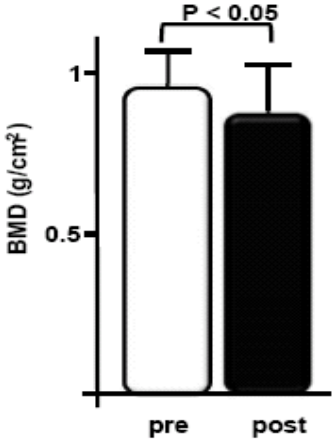

Fig. 1. Bone mineral density in pre and

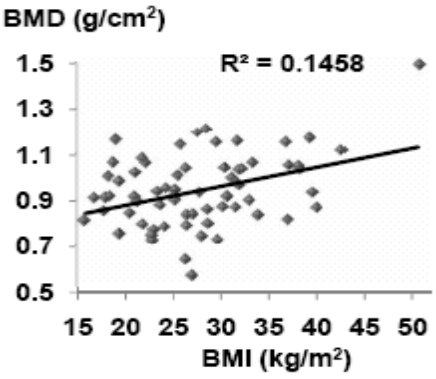

Fig. 2. Correlation between BMD and BMI

postmenopausal women

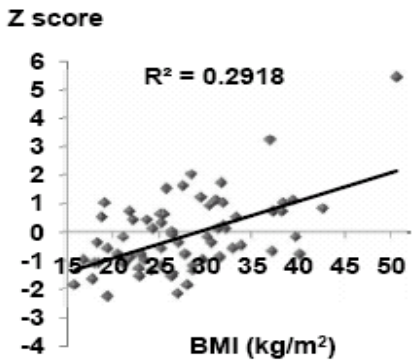

Fig. 3. Correlatona between lumbar Z score and BMI in the entire group

Adipocyte can synthesize trough aromatization estrogens from androgen precursors (3), being an important source of estrogen production and thus protecting the bone mass in postmenopausal women. In our study group we found that both estradiol (predominat estrogen secreted by ovaries) and estrone (produced by aromatization of androgens into estrogens in adipose tissue) correlated with bone mass in premenopausal women but not in the postmenopausal ones, suggesting that the alleged adipose tissue role as additional postmenopausal estrogen reservoir is negligible in keeping an adequate bone mass.

in all study women

Both estradiol and estrone positively correlated with Z score only in premenopausal women (fig. 4).

If the correlation is positive in premenopause, the same is not true in postmenopause (fig. 5).

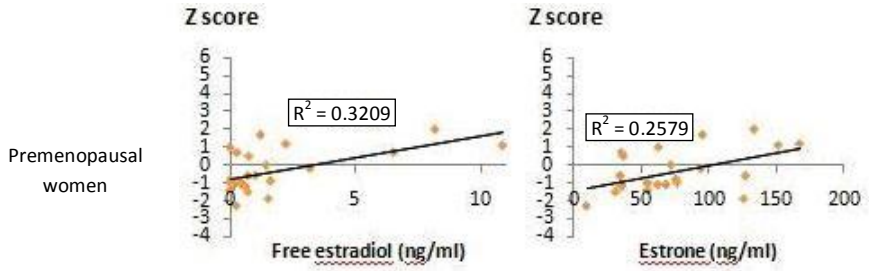

Fig. 4. Correlation between între estradiol and estrone levels and Z score in premenopausal women

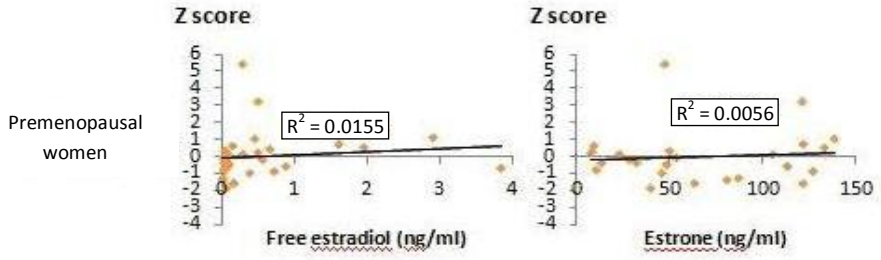

Fig. 5. Correlation between între estradiol and estrone levels and Z score in postmenopausal women

DISCUSSION

Bone mineral content is strongly influenced by menopause and estrogen depletion. Trabecular bone is characterized by high turnover, the vertebrae being the first bones in which after menopause mineral loss becomes significant (3, 4).

Body mass also influences the bone mineral content (5). Low body weight is known to be an independent risk factor for osteoporosis in pre- and post menopausal women (6). Data on adipose tissue and bone are even more conflicting, some authors suggesting that fat mass appears to be more important in bone mass prediction, especially in postmenopausal women (7).

This effect may be mediated by adipocitokine (8) or extragonadal estrogen reservoir represented by adipocytes (9). Adipocyte can synthesize through aromatization estrogen from androgen precursors (10), and thus can be an important source of estrogen for bone mass protection in postmenopausal women (11). In our study group we found that both estradiol, predominant estrogen secreted by ovaries, and estrone, produced by aromatization of androgens into estrogens in adipose tissue correlated with bone mass in premenopausal women but not in the postmenopausal ones, suggesting that the alleged role of additional postmenopausal estrogen reservoir of the adipose tissue is negligible in maintaining a suitable bone mass.

CONCLUSIONS

This clinical study shows that bone mass correlates to body weight in pre- and postmenopausal Caucasian women, most likely through a direct mass effect caused by gravitational stress. Increased body weight prevents bone loss in postmenopausal women, normal or underweight postmenopausal women having a lower BMD than premenopausal women ($p < 0,05$).

Aromatization of androgens into estrogens in the adipose tissue seems to play a significant role in osteoporotic protection of postmenopausal women ($R^2 = 0.0056$).

EFFECTIVENESS OF SELF-ADHESIVE LUTING CEMENTS IN BONDING TO CHLORHEXIDINE-TREATED DENTIN

Chlorhexidine has a broad spectrum of antibacterial action and it is claimed to serve as a potent inhibitor of endogenous collagenolytic/gelatinolytic activity of the matrix metalloproteinases, preserving the bonding integrity in adhesive restorative techniques. These properties recommend chlorhexidine as a cavity disinfectant prior to the application of restorative materials and, more recently, as a root canal irrigant. The aim of this study was to investigate the influence of dentin pre-treatment with different concentrations of chlorhexidine solutions on the microtensile bond strength and failure pattern of self-adhesive luting cements. Resin-composite (Filtek Z250, 3 M ESPE) discs (12 mm in diameter, 6.0 mm thickness) were cemented to the smear layer-covered dentin using RelyX, 3 M ESPE; Multilink Sprint, Ivoclar Vivadent, after dentin pretreatment with 0.2% or 2.0% chlorhexidine solutions. Results were compared with the control, untreated dentin. The specimens were tested in tension with a crosshead speed of 0.5 mm/min in a universal testing machine, and the failure patterns were classified. Two-way ANOVA and Tukey's tests were performed. Additionally, teeth were subjected to energy-dispersive X-ray spectroscopy (EDS) analysis and micromorphology characterization of the smear layer-covered dentin and 0.2% or 2.0% chlorhexidine-treated dentin surfaces. The microtensile bond strength obtained for both control groups were significantly higher, regardless of the chlorhexidine concentration and/or the cement used. Bond strengths were significantly higher for RelyX than for Multilink Sprint, except when 2.0% chlorhexidine was applied. Fractographic analysis indicated that most failures in the control groups occurred cohesively in the self-adhesive luting cements. Pre-treated dentin with 0.2% and 2.0% chlorhexidine solutions presented higher incidences of adhesive failures. EDS/SEM analysis exhibited varied concentrations of chlorine ions and crystal-shaped precipitates, depending upon the chlorhexidine concentration. These results suggest that pre-treatment of dentin with 0.2% or 2.0% chlorhexidine adversely affects the bonding efficacy when associated with the self-adhesive luting cements tested, probably because of the chlorine residues on the dentin surface. The benefits of application of chlorhexidine solutions prior to cementation of indirect restorations using self-luting cements should be reconsidered (Vinicius Di Hipólito, Flávia Pires Rodrigues, Fabiana Bárbara Piveta, Lídia da Cunha Azevedo, Roberta Caroline Bruschi Alonso, Nick Silikas, Ricardo Marins Carvalho, Mario Fernando De Goes, Paulo Henrique Perlatti D'Alpino. Effectiveness of self-adhesive luting cements in bonding to chlorhexidine-treated dentin. *Dental Materials* 2012; 28: 495-501).

LONG TERM PROGNOSIS OF POLYVASCULAR PATIENTS WITH ASSOCIATED CHRONIC OBSTRUCTIVE PULMONARY DISEASE (Abstract): **Objective**: To evaluate by various tools the prognosis of the polyvascular patients (defined as the presence of more than one affected vascular bed), who also associate chronic obstructive pulmonary disease. **Material and methods**: Fifty-eight patients discharged after an episode of acute cardiorespiratory failure were examined at 3 month-intervals for 1, 2 and 3 years (2010-2012). The following were performed: physical examination, biochemical and hematological tests, spirometry, electrocardiography, transthoracic echocardiography, brain computer tomography or magnetic resonance imaging. All patients in our study were smokers with chronic pulmonary obstructive disease. Treatment relied on the European recommendations for cardiac pathology and associated medical conditions. **Results:** A favorable clinical course was noticed in compliant patients. Patients with metabolic syndrome and/or old stroke, and peripheral arterial disease have a poor prognosis. A strong link seems to exist between systolic function of the right ventricle and cardiovascular mortality. The association of this condition to ischemic heart disease modifies the right ventricle hemodynamics. **Conclusions:** Polyvascular patients in acute cardiorespiratory failure have a mortality of 36% in the first 3 weeks. After 3 years, 86% of the patients survive. The modern methods of diagnosis and treatment allow improving the quality of life and increasing its duration. **Key words:** MYOCARDIAL ISCHEMIA, STROKE, PERIPHERAL ARTERIAL DISEASE.

Polyvascular disease is currently defined as a simultaneous clinical impairment of two or three arterial territories (coronary, cerebral or peripheral). As PRISMA survey shows, despite the educational measures aimed at changing lifestyle and therapeutical attitude, polyvascular patients still have a poorer control of serum cholesterol levels (1). In REACH registry (2) 68,000 vasculopathic patients were monitored for two years. Investigators found that in the polyvascular patients the carbohydrate and lipid metabolism were more difficult to control. Also, 2-year cardiovascular events were twice as frequent in polyvascular as monovascular patients. Importantly, only one of six patients had symptoms, hence the need for proper assessment of vascular damage. The same study shows that in polyvascular patients, revascularization rate was two

times higher.

Our study followed for three years (2010, 2011, and 2012) the disease course of a group of 58 polyvascular patients admitted to hospital in 2009 in critical condition after an episode of acute cardiorespiratory failure on the background of chronic respiratory disease. The systolic dysfunction of right ventricle was associated with more frequent cardiovascular events.

MATERIALS AND METHODS

The study included 58 patients, 34 males and 24 female. Patients' age at the beginning of the study ranged between 52 and 82 years. We performed a spirometry on all patients, when included in the study. This method established the stage of the chronic obstructive pulmonary disease (according to the GOLD criteria – Global Initiative for Chronic Obstructive Lung Disease). The recommended treatment for chronic respiratory disease consisted of: inhaled parasympaticolytics (Tiotropium 18μg), association of inhaled sympathomimetics and corticosteroids (50 μg Salmeterol / Fluticasone 125-500 μg), Theophylline retard 350mg and oxygen therapy at home, 4-6 l / min, 6-8 hours / day, intermittently if the patient is GOLD stage IV.

All patients were subjected to cardiovascular assessment: immediate blood pressure measurement in supine position in both arms and in standing position, and 5 minutes later in orthostatic position, cardiac auscultation, palpation and auscultation of carotid and subclavian arteries, abdominal aorta, renal, femoral, and popliteal arteries, pulmonary auscultation, jugular inspection, detection of hepato-jugular reflux and lower limbs edema.

Resting electrocardiogram was performed with a Heart Screen HS60G device for all patients, every 3 months during the three follow up years. Right and posterior chest leads were also used. Transthoracic echocardiography was performed with a Fukuda Denshi UF-850 XTD echocardiograph. Peripheral arterial damage was confirmed by arterial Doppler, while the evaluation of cerebral complications was studied with brain computer tomography or magnetic resonance imaging.

For cardiovascular diseases, the patients received dual antiplatelet therapy (Aspirin 75mg and Clopidogrel 75 mg) as recommended by CHARISMA study (3,4), statins (Atorvastatin 40-80 mg, dosage varying according to patient's tolerance, muscle mass and the degree of nitrogen retention), cardioselective beta-blockers (5-10 mg Nebivolol, Carvedilol 12.5 mg), angiotensin converting enzyme (Perindopril 5-10 mg) or sartan (Telmisartan 40-80 mg), fixed drug combinations (Perindopril 5 mg /Indapamide 1.5 mg), combination of diuretics (Furosemide 20 mg + Spironolactone 50 mg) - in congestive heart failure.

RESULTS

In regards to chronic obstructive pulmonary disease, seven patients (12%) were in GOLD stage II, 14 patients (24%) in GOLD stage III, and 37 patients (62%) in GOLD stage IV.

Forty-seven patients (82%) were diagnosed with arterial hypertension, 6 patients (10%) with orthostatic hypotension, and the latter requiring special therapeutic attention upon prescribing hemodynamically active medication. Baseline congestive heart failure features were found in 20 patients (34%). Pathological heart murmurs were detected in 45% of patients (26 patients).

Biochemical test results revealed that the polyvascular patients more frequently

presented mixed dyslipidaemia (higher total serum cholesterol and triglycerides levels), this feature being due to the frequent association of metabolic syndrome in the patients with this condition (2).

The most common electrocardiographic finding was ST depression and negative T waves, consistent with changes suggesting trivascular coronary disease (37 patients, 35%). The remaining patients showed electrocardiographic features characteristic of myocardial necrosis (myocardial infarction in chronic stage). Right ventricular ischemic injury was revealed for 80% of the patients by the changes in right chest leads, and supported by the echocardiographic changes. Special attention was given to echocardiographic exploration of the right ventricular damage (right ventricular parietal kinetics, M-mode tricuspid annulus systolic motion, systolic pulmonary flow acceleration time, pulmonary artery systolic pressure). Perhaps, the more common association of right heart ischemia in polyvascular patients is due to hemodynamic overload induced by chronic obstructive pulmonary hemodynamic.

Echocardiographic examination of the left ventricle revealed ischemic dilated cardiomyopathy in 35 patients (60%), segmental parietal kinetic changes in 20 patients (35%), and isolated diastolic dysfunction in 3 patients (5%). Cardiac murmurs, detected at physical examination in 26 patients (25%) were confirmed echocardiographically as being mild or moderate, mitral and/or aortic valvular disease.

Peripheral arterial Doppler detected critical stenosis in 40 patients (70%), and features of atheromatosis without stenosing lesions in 15% of patients (9 patients). Cerebral arterial damage - old ischemic stroke - was detected in 38 patients (65%).

Interventional and/or surgical myocardial revascularization was required by 30% of patients (17 patients); 45% of patients underwent aorto-femoral bypass.

Vascular pathology in the study group was associated with 2 or 3 arterial territories (fig. 1).

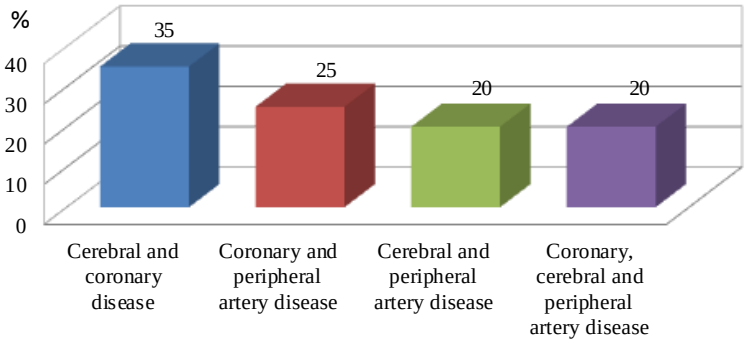

Fig. 1. Bi- or trivascular disease of the patients

Long-term prognosis was marked by an increased rate of cardiovascular events in patients with peripheral arterial disease (23 patients, 41%) after the 3 follow up years.

It is worth mentioning that arterial, myocardial, or peripheral revascularization was required at baseline by 16 patients; the other 10 patients underwent revascularization 3 to 25 months from baseline.

The incidence of metabolic syndrome in the study patients was observed in 49 patients (85%); diabetes mellitus was diagnosed in 46% of patients (26), and diabetic nephropathy was confirmed in 27% of patients (15). These three conditions associated with polyvascular disease in our study patients fed a poor prognosis (fig. 2).

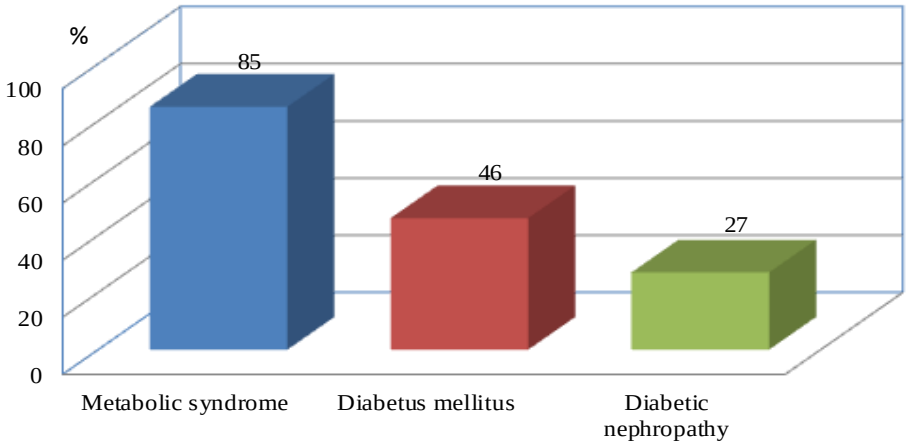

Fig. 2. The incidence of unfavorable prognostic factors in polyvascular patients

At the end of the 3 year follow-up, the cardiovascular mortality was of 14% (8 patients: 5 by acute myocardial infarction and 3 by stroke).

DISCUSSION

As noted by Criqui et al (5), peripheral arterial disease is an early indicator of cardiovascular mortality. In our study, the polyvascular patients with peripheral arterial disease presented an increase in the severity of coronary or cerebral ischemic pathology, requiring sustained therapeutic intervention.

In 2009, Deepak et al (6) published the results of CRUSADE registry, which enrolled 111,972 patients with polyvascular disease. They reported that polyvascular patients have a higher risk for cardiovascular events compared with monovascular patients. It is necessary that we continue this study by comparing the frequency of cardiovascular events in monovascular versus polyvascular patients.

Steg et al (7) participated in REACH study. They noted, like Deepak, that polyvascular patients have a higher risk for cardiovascular events than monovascular patients, since the first year of medical monitoring.

CONCLUSIONS

Our study concluded that polyvascular patients with systolic dysfunction of the right ventricle (80%) had a worse long-term prognosis than those without this dysfunction (20%). Even affected by right ventricle disease, our patients had a survival rate of 86%, 3 years after the study. The high survival rate is due to the modern

methods of diagnostics and treatment, which were applied on our patients for both cardiorespiratory diseases (medical, interventional and surgical). In addition, we remarked an improvement of the quality of life for the patients in our study.

NEWS

SMOKING AND THE RISK FOR DEMENTIA

Smoking is a possible risk factor for dementia. A new cohort study examined the association between smoking history and cognitive decline in early old age. The cognitive function was investigated using a series of 5 tests (memory, vocabulary, executive function composed of 1 reasoning and 2 fluency tests). The assessment has been made regularly for a 10 years period. For middle-aged men, the results show that the faster cognitive decline (in global cognition and executive function) was observed among current smokers compared with never smokers. For ex-smokers, with at least a 10-year cessation, the decline in executive function was similar to that among never smokers. The rate of cognitive decline among women was not affected by smoking. These new research showed that middle-aged male smokers are more likely to have a faster cognitive decline (Séverine Sabia, Alexis Elbaz, Aline Dugravot et al. Impact of Smoking on Cognitive Decline in Early Old Age The Whitehall II Cohort Study. *Arch Gen Psychiatry*. 2012; 69(6):627-635).

CERCETĂRI PENTRU EVALUAREA UNOR ELEMENTE DE ORIENTARE A DIAGNOSTICULUI ÎN CANCERUL GASTRIC

L. Gavril[1]., A. Cotîrleț[2], G. I. Maftei[3], Doina Azoicăi[3]

1. Doctorand al Universității de Medicină şi Farmacie „Grigore T. Popa" Iaşi,
2. Secția de Chirurgie a Spitalului Municipal de Urgență Moinești, județul Bacău
Universitatea de Medicină şi Farmacie „Grigore T. Popa" Iaşi
Facultatea de Medicină
3. Disciplina de Asistență Primară a Stării de Sănătate şi Epidemiologie

INVESTIGATIONS FOR ASSESSING OF SOME ELEMENTS SUGGESTIVE FOR A DIAGNOSIS OF GASTRIC CANCER (Abstract). **Aim:** Based on new data, this investigation aimed at emphasizing the importance and the medical and socio-economic implications of an early diagnosis in gastric cancer. **Material and methods:** The study included a series of 77 patients with gastric cancer admitted and treated at the surgical department of the Moineşti Municipal Emergency Hospital in the interval 2000-2010. Patients' data were obtained by clinical-epidemiological inquiry, laboratory and imaging investigations, and official statistical reports. Epidemiological and statistic-mathematical methods were used to process and interpret the collected data. **Results and conclusions:** Hemoglobin and hematocrit levels as well as the presence of anti-*Helicobacter pylori* antibodies were determined by laboratory tests. Barium sulfate X-ray examination was performed in 52% of our patients; endoscopy concurrent with the histo-pathological examination of gastric biopsy samples showed that most tumors were of vegetative and ulcerative type, being prevalently located in the antropyloric area and lesser gastric curvature. Computer tomography proved to be the method of choice for tumor dissemination and staging. The late diagnosis of gastric cancer, with aggressive forms and poor prognosis, suggests the need of preventive population screening programs. **Key words:** GASTRIC CANCER, TUMOR MARKERS, ENDOSCOPY, CANCER SCREENING

Cancerul gastric (CG), ca şi alte forme de neoplazie, ridică importante obstacole în stabilirea precoce a unui diagnostic care să favorizeze reducerea impactului medical şi socio-economic, adesea sever (1, 2).

Simptomatologia clinică, necaracteristică, este tolerată şi ignorată perioade lungi de timp şi, astfel, adresabilitatea la medic este tardivă.

În acest context, mai ales pentru persoanele cu risc crescut, explorările paraclinice, între care cele imagistice, au un rol esențial pentru depistarea precoce a CG într-un stadiu favorabil intervențiilor terapeutice.

MATERIAL ŞI METODE

Studiul se referă la un lot de 77 pacienți cu cancer gastric asistați în secția de chirurgie a Spitalului Municipal de Urgență Moinești, județul Bacău, în perioada 2000-2010.

Pentru caracterizarea pacienților incluşi

în studiu s-au acumulat informaţii printr-o anchetă clinico-epidemiologică special concepută, precum şi cele oferite de evidenţele statistice oficiale ale spitalului.

Evaluarea diagnosticului paraclinic s-a realizat prin investigarea valorilor hemoglobinei (Hb), hematocritului (Ht), prezenţa anticorpilor anti-*Helicobacter pylori*, markerii tumorali (CA 19-9; AFP; CA 125; TPSA; CA 15-3) şi rezultatele examenului imagistic (radiologic, endoscopic, eco-endoscopic, computer tomografic şi cel pentru stadiile invaziei ganglionare).

Prelucrarea şi interpretarea datelor s-a realizat prin metode epidemiologice (ancheta, tabularea, incidenţa, prevalenţa, reprezentările grafice) şi statistico-matematice – aplicaţia *Epi Info* (regresia liniară, diferenţa standard, t-Student, χ^2).

REZULTATE

1. Investigaţiile de laborator au evidenţiat că valorile hemoglobinei (Hb) au variat între 4,19-14g/dl cu o medie de 9,77g/dl; hematocritul (Ht) a înregistrat un nivel de 13,1-52% cu o medie de 32,39% (tab. I).

TABELUL I

Limitele valorilor hemoglobinei şi hematocritului la bolnavii cu cancer gastric incluşi în studiu

Parametrii	Nivelurile		
	Minim	Mediu	Maxim
Hemoglobina (g/dl)	4,19	9,77	14,00
Hematocritul (%)	13,1	32,39	52,00

Aceşti indicatori pot marca intensitatea modificărilor determinate de procesul neoplazic şi astfel, orientează natura evoluţiei şi a prognosticului (3,4).

Implicarea *Helicobacter pylori* în favorizarea declanşării carcinogenezei la nivelul mucoasei gastrice poate fi luată în discuţie ca urmare a evidenţierii prezenţei anticorpilor specifici la 17 (22%) bolnavi din lotul studiat (5).

În studiul nostru, pentru diagnosticul şi prognosticul bolii s-au analizat şi următorii markeri tumorali: CA 19-9: Antigenul carbohidrat CA 19-9; AFP: alfa-fetoproteina; CA 125: Antigenul carbohidrat CA 125; TPSA: Antigenul prostatic specific si CA 15-3: Antigenul carbohidrat CA 15-3 (tab. II).

TABELUL II

Valorile unor markeri tumorali evidenţiaţi la 12 pacienţi cu cancer gastric

Marker	Lotul de studiu			
	Nr.	% (x)	Valori	
			Normale	Crescute
CA 19-9	1	1,3	1	-
AFP	2	2,6	2	-
CA 125	3	3,9	3	-
TPSA	3	3,9	1	2
CA 15-3	3	3,9	3	-

(x) Pentru valorile mai mici de 10, proporţiile sunt orientative

2. Investigațiile imagistice.

2.1. Examenul radiologic s-a efectuat la 40 (52%) pacienți, cel mai frecvent investigarea a folosit sistemul dublu contrast, cu o compresiune moderata şi ingestie de sulfat de bariu cu densitate mare. În stadiul incipient, modificările radiologice au fost minime, iar în forma avansată s-au înregistrat schimbări ale reliefului mucoasei şi ale peristalticii gastrice (6,7,8).

2.2. Examenul endoscopic a permis evaluarea aspectului macroscopic şi localizarea leziunilor mucoasei gastrice. Astfel, s-a constatat că zona antro-pilorică a înregistrat în peste o treime din cazuri proliferări epiteliale neoplazice maligne. Date similare au fost semnalate şi de alți autori (8,9,10) (tab. III).

TABELUL III

Distribuția pe zone anatomice a leziunilor din cancerul gastric, la lotul inclus în studiu

Tipul leziunii	Zona anatomică	Cazuri	
		Nr.	% (x)
Primitivă	Eso-cardială	6	7,8
	Corp gastric+Fornix	13	16,9
	Mica curbură	21	27,2
	Marea curbură	3	3,9
	Antro-pilorică	**32**	**41,6**
Total		75	97,4
Recidivă	Bont gastric	1	1,3
	Gura de anastomoză	1	1,3
Total		2	2,6

(x)Pentru valorile mai mici de 10, proporțiile sunt orientative

În peste 80% din cazurile studiate, s-a evidențiat endoscopic localizarea tumorii neoplazice la un singur segment gastric. La ceilalți bolnavi, tumora s-a extins în ordine descrescătoare, spre corpul gastric, mica curbură şi în regiunea eso-cardială (tab. III).

2.3. Examenul ecoendoscopic a fost efectuat la 81,8% dintre pacienți şi a permis evaluarea gradului de invazie a peretelui gastric (T), afectarea ganglionilor regionali (N) şi invazia la distanță (M). A rezultat că 49,2% din cazuri s-au încadrat în faza a III-a de invazie, cu invadarea integrală a peretelui gastric fără a depaşi seroasa peritoneală (tab. IV).

TABELUL IV

Distribuția în raport cu nivelurile invaziei peretelui gastric evidențiată ecoendoscopic, la 63 bolnavi cu cancer gastric

Tip de invazie (T)	Cazuri	
	Nr.	% (x)
Tipul I	4	6,3
Tipul II	11	17,5
Tipul III	31	**49,2**
Tipul IV	17	27
TOTAL	63	100

(x)Pentru valorile mai mici de 10, proporțiile sunt orientative

Investigația ecoendoscopică a dovedit a avea o valoare limitată în a identifica diseminarea la distanță a procesului canceros. În studiul nostru, numai 6 (9,5%) pacienți din sublotul de 63 au prezentat diseminări secundare, la nivel hepatic şi a seroasei peritoneale (9,10,11).

2.4. Examenul computer-tomografic a fost practicat la 18 (23,4%) pacienți şi a evidențiat, pentru 2/3 din cazuri, extinderea procesului tumoral în structurile din vecinătatea peretelui gastric. A rezultat că 78% din tumori se încadrează în stadiile III şi IV de invazie, 75% cu determinări ganglionare şi 34 % cu metastaze evidente (tab. V).

TABELUL V

Distribuția celor 18 cazuri de cancer gastric examinate computer-tomografic, în relație cu stadiul de gravitate (T= afectarea peretelui gastric; N= interesarea ganglionilor regionali; M= diseminarea la distanță)

Stadiul afectării (TNM)	Nr.	% (x)
I A	1	5,56
I B	4	22,22
II A	1	5,56
II B	2	11,11
III A	3	16,66
III B	1	5,56
IV	**6**	**33,33**
TOTAL	18	100

(x)Pentru valorile mai mici de 10, proporțiile sunt orientative

3. Investigații morfopatologice.

3.1. Aspectele macroscopice au evidențiat pe toate piesele de exereză chirurgicală, elemente semnalate şi de alți autori (11). Astfel, ponderea localizării proximale a CG a fost de numai 5% pentru întregul lot care a beneficiat de examen endoscopic, şi de aproximativ 8% în cazul pacienților supuşi intervenției chirurgicale. Extensia tumorilor la mai mult de un segment gastric a fost prezentă, în lotul nostru, la aproximativ 20% din cazuri, comparativ cu alți autori care au găsit valori de până la 6% (12).

Distribuția cazurilor de CG studiate în raport cu diferitele localizări şi aspecte macroscopice au evidențiat valori similare cu cele semnalate în Europa, dar diferite de cele din Asia, unde există un risc mai semnificativ de apariție a acestui tip de cancer (13).

3.2. Aspectele microscopice studiate, folosind piesele rezultate din actele operatorii, au fost analizate în raport cu elementele sistemului de clasificare OMS şi au evidențiat că forma tubulară a fost prezentă în 41,6% din cazuri, incluzând, îndeosebi, CG moderat diferențiate.

Folosind sistemul de clasificare Laurén, peste 50% din tumori s-au încadrat în categoria "difuză" şi 35% în cea de tip "intestinal" (14) (tab. VI).

TABELUL VI

Distribuția cazurilor de cancer gastric, în lotul studiat, în relație cu aspectul microscopic

Tipuri ale aspectului microscopic	Cazuri	
	Nr.	% (x)
Tubular	32	41,6
Papilar	7	9
Mucinos	13	16,9
Cu celule în "Inel cu pecete"	19	24,7
Nediferențiat	6	7,8
TOTAL	77	100

(x)Pentru valorile mai mici de 10, proporțiile sunt orientative

DISCUȚII

Explorările de laborator, imagistice şi anatomopatologice aduc un aport asociativ esențial în evaluarea cazurilor de CG, atât în formele inițiale cât şi in cele avansate, permițând creşterea eficientei stabilirii diagnosticului, prognosticului si a conduitei terapeutice.

Continua sa aibă prioritate examenul radiologic gastric cu sulfat de bariu, care poate evidenția triada: nişa, lacuna, infiltrație (1,2).

Endoscopia digestiva superioara poate vizualiza un CG inițial, permite prelevarea biopsiilor de mucoasa gastrica, supravegherea in dinamica a stărilor precanceroase: gastrita atrofică cu metaplazie intestinala, anemia pernicioasa, polipii gastrici, stomacul rezecat, displazia gastrica (9).

Endoscopia gastrica cu magnificație asociază examenului endoscopic clasic un proces de mărire a imaginii de pana la 150 ori prin utilizarea unui sistem optic care se comportă ca un microscop de înaltă rezoluție. În aceste condiții pot fi evaluate, cu acuratețe, modificările macroscopice identificate la examenul endoscopic (11).

Ecoendoscopia combină endoscopia digestivă superioară cu ecografia prin ataşarea la vârful endoscopului a unui transductor ultrasonografic, fiind astfel posibilă vizualizarea peretelui gastric şi a structurilor adiacente (10,11).

Computer tomografia gastrică are o acurațe mai redusă în ce priveşte CG inițial, în special tipul plat dar este superioară celorlalte metode imagistice pentru diagnosticul formelor avansate şi permite evaluări ale prognosticului, contribuind la realizarea stadializarii TNM (T- profunzimea tumorii primare; N- afectarea ganglionilor regionali; M- metastazele la distanță) (10).

CONCLUZII

Investigațiile de laborator au evidențiat date privind nivelurile hemoglobinei, hematocritului, markerilor tumorali, prezența anticorpilor anti-*Helicobacter pylori*. Pentru 52% dintre pacienții incluşi în studiu s-a efectuat examenul radiologic, cu ingestia sulfatului de bariu cu densitate mare, cu o compresiune moderată sau dublu contrast reuşindu-se astfel evidențierea modificării reliefului mucoasei şi a peristalticii, fiind posibilă stabilirea diagnosticului sau a suspiciunii de CG.

Examenul endoscopic combinat cu cel histopatologic al prelevatelor prin biopsie gastrică a permis conturarea unui profil morfologic particular al lotului de pacienți evaluați. S-a stabilit că tumorile studiate au

fost, în general, de tip vegetant şi ulcerat, cu localizare predilectă la nivelul regiunii antro-pilorice, a micii curburi şi a feţelor anterioară şi posterioară ale corpului gastric, cu caracter extensiv şi cu predominanţa formelor slab şi moderat diferenţiate.

Investigaţia gastrică computer tomografică s-a dovedit a fi metoda de elecţie pentru evaluarea diseminării la distanţă a procesului tumoral, dar pentru completa caracterizare a CG s-a impus şi efectuarea unui examen endoscopic combinat cu cel histopatologic al fragmentelor de mucoasă gastrică prelevate prin biopsie şi stadializarea tumorii în sistemul TNM.

Predominanţa unui diagnostic tardiv al CG, existenţa unor forme agresive şi a unui prognostic sever sugerează necesitatea continuării unor preocupări asociativ multidisciplinare pentru elaborarea şi realizarea de programe pentru un *screening* populaţional prevenţional.

ETIOLOGIA PNEUMONIEI ASOCIATĂ VENTILAȚIEI MECANICE LA CLINICA DE CHIRURGIE CARDIOVASCULARĂ DIN IAŞI

Raluca Ioana Şerban[1], Maria Dan[2], Carmen Valentina Pânzaru[2], Diana Anghel[2], D.M. Dăscălescu[2], Liliana Ciucu[2], I. Şerban[3], G. Tinică[2]

1. Doctorand al Universității de Medicină și Farmacie „Grigore T. Popa" - Iaşi
2. Institutul de Boli Cardiovasculare - Iaşi
3. Casa de Asigurări de Sănătate - Iaşi

ETIOLOGY OF VENTILATOR-ASSOCIATED PNEUMONIA AT THE CARDIO-VASCULAR SURGERY CLINIC OF IASI (Abstract): **Aim**: We want to assess the etiology of ventilator-associated pneumonia (VAP) and emergence of resistant phenotypes for greater efficiency of the first-line antimicrobial treatment post-cardiac surgery. The study focuses on patients with VAP post-cardiac surgery at the Institute of Cardiovascular Surgery between April 2nd 2002 and August 27th 2008, divided in two groups, before and after June 14th, 2005. **Material and methods**: The tracheal aspirates were examined quantitatively (microscopy, culture). The isolates with clinical significance (≥ 106 CFU/mL) were identified by standard methods and tested by disk difussion or with the breakpoints method for susceptibility to antibiotics. **Results**: Among the 1527 operated patients, 28 of them were diagnosed with VAP through the clinical pulmonary infection score ≥ 6. The 9 most common pathogens in VAP etiology were Pseudomonas aeruginosa 23.81%, Acinetobacter baumannii 19.05%, Stenotrophomonas maltophilia 11.91%, Candida albicans 9.53%, while Klebsiella pneumoniae, Escherichia coli, Staphylococcus aureus, Corynebacterium striatum/amycolatum, Pneumocystis jirovecii amounted 4.76% each. Acinetobacter baumannii and S.maltophilia appear starting with June 15th, 2005. From that moment on we isolated with a higher frequency the gram-negative bacilli which produce extended-spectrum beta-lactamases 15.62%, with multidrug resistance (MDR) 46.86%. The MDR phenotype was more frequent at A.baumannii (15.62%), S.maltophilia (15.62%) and P.aeruginosa (12.50%) compared to K.pneumoniae (3.12%) or E.coli (0%). Methicillin-resistant S. aureus was isolated with a 6.25% frequency. **Conclusions**: The most common etiologic agents of ventilator-associated pneumonia post-cardiac surgery are Pseudomonas aeruginosa, Acinetobacter baumannii, Stenotrophomonas maltophilia and Candida albicans. The large use of antibiotics selects infectious agents with intrinsic resistance and multiresistant phenotypes. **Key words**: ETIOLOGY, VENTILATOR-ASSOCIATED PNEUMONIA, CARDIAC SURGERY.

Pneumonia asociată ventilației mecanice (PAV) este o infecție nosocomială majoră la pacienții din unități de terapie intensivă (UTI), iar agenții diferă pentru fiecare unitate (1, 2). În UTI post-chirurgie cardiacă, PAV reprezintă cea mai frecventă infecție nosocomială (3), cu mortalitate care poate ajunge la 76% (2).

În acest studiu am evaluat etiologia PAV și emergența microorganismelor antibioticorezistente în UTI a clinicii de chirurgie cardiovasculară din Institutul de Boli

Cardiovasculare din Iaşi (IBCVI) pentru a creşte eficienţa tratamentului antimicrobian de primă intenţie la pacienţii suspectaţi de PAV post-operator.

MATERIAL ŞI METODE

Studiul retrospectiv s-a realizat pe un lot de 28 pacienţi diagnosticaţi cu PAV post-chirurgie cardiacă cu *by-pass* cardiopulmonar (BCP) la IBCVI în perioada 2002-2008. Am analizat comparativ două intervale egale, marcate prin data izolării în UTI a primei tulpini multirezistente de *Acinetobacter baumannii*.

Eligibili au fost pacienţii cu vârsta ≥ 18 ani, cu VM ≥ 48 ore şi PAV confirmată microbiologic. Studiul a fost aprobat de Comisia de Etică a IBCVI.

Aspiratele traheale (AT) au fost examinate cantitativ (microscopie şi cultură) (4). Identificarea izolatelor a fost realizată prin metode standard şi sistemul comercial API bioMérieux. Sensibilitatea la antibiotice am testat-o difuzimetric (5) sau prin metoda punctelor de ruptură pe galerii API cu citire spectrofotometrică (mini API - bioMérieux).

Pneumonia asociată ventilaţiei mecanice (un episod) a fost diagnosticată prin scorul clinic de infecţie pulmonară (SCIP) ≥ 6 (6). Cazurile de PAV au fost confirmate microbiologic prin izolarea cantitativă a cel puţin unui microorganism condiţionat patogen cu pragul cantitativ $\geq 10^6$ UFC/mL (7) ce s-a regăsit semnificativ asociat celulelor inflamatorii în culturile din AT (4). Hemoculturile pozitive cu aceeaşi tulpină izolată din AT au confirmat etiologia PAV. Semnificaţia clinică pentru *Pneumocystis jirovecii*, fung necultivabil, a fost stabilită de asocierea semnificativă a chiştilor şi formelor trofice cu celulele inflamatorii pe frotiul Giemsa din AT (4).

Rezistenţa multiplă la antibiotice (RMA) este definită doar pentru bacilii Gram-negativ (BGN) ca rezistenţa la cel puţin o cefalosporină (ceftriaxonă/cefotaxim/ceftazidim), un aminoglicozid (amikacină/tobramicină) şi ciprofloxacin (8).

Doze zilnice prescrise (DZP) reprezintă frecvenţa cumulată a dozelor zilnice de agenţi antimicrobieni prescrişi după natura acestora (9).

Variabilele cantitative le-am analizat cu testele χ^2 şi exact Fisher. Variabilele continui le-am exprimat prin medie ± deviaţie standard. Programele utilizate au fost Excel 2007 şi SPSS 16 (pentru validare). Semnificaţia statistică a fost stabilită pentru $p < 0.05$. Pentru fiecare episod PAV a fost consemnată data apariţiei şi tipul agentului patogen implicat; apoi, tratând timpul ca o variabilă statistică continuă am calculat distribuţia temporală (utilizând o distribuţie Student) pentru fenotipurile rezistente. În acest caz variabila temporală utilizată este purtătoarea informaţiei utile, intervalul de încredere (determinat pentru $p = 0.05$) reprezentând perioada de emergenţă în UTI a acelui tip de microorganism (caracterizată de un moment de apariţie, un moment de dispariţie din UTI, şi un maxim al probabilităţii de incidenţă). Dacă intervalul de încredere depăşeşte perioada analizată, am calculat probabilitatea de eroare totală rezultată.

REZULTATE

În cei 6 ani au fost operaţi 1527 de pacienţi, 673 înainte de 14.06.2005, iar 854 după această dată. Postoperator, 28 au fost confirmaţi cu PAV.

Din datele demografice, vârsta medie a celor 28 de pacienţi studiaţi a fost 57,4 ± 15,4 ani. Dintre comorbidităţi, insuficienţa cardiacă (IC) a fost prezentă la 26 (92,86%) pacienţi. Douăzeci şi şase (92,86%) din 28 de pacienţi au fost spitalizaţi ≥ 5 zile la IBCVI până la debutul PAV. Cinci pacienţi din 28 (17,86%) au primit terapie antibac-

teriană înainte de operație (în ultimele 90 de zile anterioare intervenției). Hemoculturi pozitive, cu același microorganism identificat în aspiratul traheal, au avut 5 (17,86%) dintre pacienți.

Cei 28 de pacienți au avut 35 episoade de PAV care au fost monomicrobiene 28 (80%) și posibil mixte 7 (20%). Am izolat 42 de tulpini, iar cei mai comuni 9 patogeni ai PAV au fost: *P. aeruginosa* 23,81%, *A. baumannii* 19,05%, *S. maltophilia* 11,91%, *C. albicans* 9,53%, iar *K. pneumoniae*, *E. coli*, *S. aureus*, *C. striatum/amycolatum*, *P. jirovecii* fiecare în procent de 4,76% (tab. I).

TABELUL I

Etiologia PAV în perioada 02.04.2002-27.08.2008

Agenții etiologici ai PAV	**Înainte de 14.06.2005**	**După 14.06.2005**	**Numărul total**	**% total**
P.aeruginosa	5	5	10	23.81
A.baumannii	0	8	8	19.05
S. maltophilia	0	5	5	11.91
C. albicans	2	2	4	9.53

Cu o frecvență de 23,81% fungii ocupă locul 2 după BGN nefermentativi 54,77%. *Acinetobacter baumannii* și *S.maltophilia* au apărut începând cu 15.06.2005. După această dată am izolat cu frecvență crescută BGN care produc β-lactamaze cu spectru extins (BLSE) 15,62% și cu RMA 46,86%. Fenotipul RMA a fost mai frecvent la *A. baumannii* (15,62%), *S.maltophilia* (15,62%) și *P.aeruginosa* (12,5%) comparativ cu *K.pneumoniae* (3,12%) sau *E.coli* (0%). *Staphylococcus aureus* meticilino-rezistent a fost izolat cu frecvență de 6,25% (fig. 1).

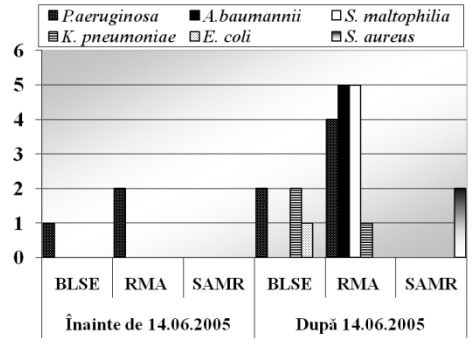

Fig. 1. Emergența speciilor de *A.baumannii* și *S.maltophilia*, creșterea prevalenței fenotipurilor rezistente în etiologia PAV

Am evaluat statistic implicarea fenotipurilor rezistente în etiologia PAV (fig. 2, tab. II, tab. III).

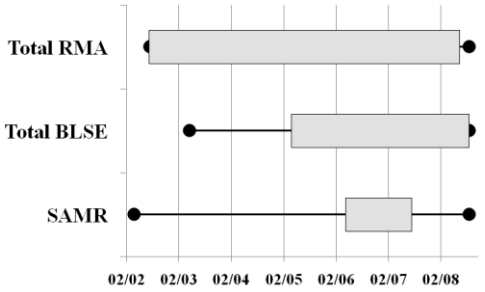

Fig. 2. Distribuția Student

Cei 28 de pacienți au primit antibiotice (1168 DZP): *preoperator*, 5 pacienți (17,86%) au primit tratament antibiotic (116 DZP – 92 DZP antibacteriene şi 24 DZP antifungice); *intraoperator* şi *postoperator* toți pacienții au primit antibiotice până la debutul PAV (1052 DZP – 803 DZP antibacteriene şi 249 DZP antifungice).

DISCUȚII

Etiologia PAV în majoritatea episoadelor include organisme oportuniste ale fondului microbian de spital. Pentru tratamentul antibiotic de primointenție este esențial să fie cunoscut spectrul etiologic local şi sensibilitatea la antibiotice (1, 2).

Prin acest studiu retrospectiv am furnizat informații medicilor intensiviști cu privire la modificarea fondului microbiologic, prin emergența speciilor de *A.baumannii, S.maltophilia* şi creşterea prevalenței fungilor.

TABELUL II

BGN, bacili Gram-negativ;
˚, Rezistent; [1],*P.aeruginosa*; [2], *P.aeruginosa, A.baumannii, S.malthophilia*;
[3], *E.coli, K.pneumoniae*; [4], *K. pneumoniae*; *, limitat de perioada analizată (02.04.2002-27.08.2008).

La IBCVI, bacilii Gram-negativ (64,29%) s-au dovedit a fi cel mai frecvent implicați în PAV, ceea ce se corelează cu rezultatele obținute de Chastre şi Fagon (2) - 48,1% sau Rello et al. (10): Montevideo (62,04%), Barcelona (58,73%), Paris (51,87%) şi Sevilla (52,71%). În contrast, distribuția şi prezența acestora (tab. IV), dar şi a celor-lalți agenți etiologici ai PAV este diferită pentru fiecare UTI (10). Toate aceste date susțin afirmația: fiecare UTI are un spectru etiologic propriu (1, 2). În studiul nostru, fungii (23,81%) ocupă locul 2 în etiologia PAV. Datele noastre sunt similare cu cele obținute de Wójkowska et al (11) în 2009: cei mai comuni agenți etiologici ai PAV după chirurgie coronariană sunt BGN (52,2%) şi fungii (14,6%).

TABELUL IV

Variația distribuției agenților etiologici în PAV

Agenții etiologici	M* (10)	B* (10)	P* (10)	S* (10)	IBCVI
P.aeruginosa %	13,28	52,44	15,91	14,54	23,81
A.baumannii %	18,69	0	8,98	27,27	19,05
S.maltophilia %	6,5	0	2,49	0	11,91
Enterobacteriaceae %	23,57	6,29	24,49	10,9	9,52
S. aureus (%)	17,89	11,18	21,22	18,18	4,76

* Montevideo, Barcelona, Paris, Sevilla.

Incidența în creştere a BGN în etiologia PAV la IBCVI, de la 50% în prima perioadă la 68,75% în a doua perioadă, a fost însoțită de emergența tulpinilor rezistente şi multirezistente la antibiotice: pentru tulpinile producătoare de BLSE de la 10% la 15,62%, iar pentru RMA de la 20% la 46,86%. *Pseudomonas aeruginosa* a fost singurul BGN prezent în prima perioadă: BLSE 10% şi RMA 20%. După 14.06.2005, odată cu apariția speciilor de *A. baumannii* şi *S. malthophilia* am constatat creşterea prevalenței fenotipului RMA (46,86%), fiind mai frecvent la *A.baumannii* (0%-15,62%), *S.maltophilia* (0%-15,62%) față de *P.aeruginosa* (20%-12,5%), *K.pneumoniae* (0%-3,12%) şi *E.coli* (0%-0%). În a doua perioadă fenotipul BLSE (15,62%) a fost mai frecvent la *K.pneumoniae* (0%-6,25%) şi *E.coli* (0%-3,12%) comparativ cu *P.aeruginosa* (10%-6,25%), iar SAMR a crescut de la 0% la 6,25%.

Majoritatea pacienților (92,86%) au fost spitalizați în IBCVI cel puțin 5 zile înainte de operație şi au prezentat IC. Toți au avut intervenții cu BCP şi au primit antibiotice până la debutul PAV.

Terapia antimicrobiană în ultimele 90 de zile, spitalizarea actuală de cel puțin 5 zile şi imunosupresia, sunt factori de risc pentru implicarea unui patogen cu rezistență la antibiotice (1). Pacienți imunodeprimați sunt şi cei cu IC (12), iar operațiile efectuate cu BCP determină o supresie temporară a imunității începând din ziua 1 până în ziua 3-5 postoperator (13). În plus, terapia cu antibiotice are un rol major în selectarea microorganismelor cu rezistență intrinsecă (*P.aeruginosa*, fungi) sau dobândită (2).

Emergența speciilor de *A.baumannii*, *S.maltophilia* a condus la creşterea prevalenței tulpinilor cu fenotipul RMA în UTI post-chirurgie cardiacă de la IBCVI.

Rezultatele testelor χ^2 şi exact Fisher nu pot preciza semnificativ statistic ($p<0.05$) apartenența *strict* la una din perioade a niciunui fenotip implicat în etiologia PAV. Rezultatele arată totuşi tendința de creştere a numărului de apariții după 14.06.2005 a fenotipurilor RMA şi, ca o consecință totalitatea BGN rezistenți (Total BGN R), datorită valorilor crescute pentru χ^2 şi corespunzător coborâte pentru p (Fisher) (tab. II).

Prin analiza distribuției Student, se pot identifica uşor fenotipurile pentru care nu se poate pune în evidență o evoluție în sensul "apariției" respectiv "dispariției" din UTI a fenotipului respectiv deoarece limitele intervalului de încredere ($p = 0.05$) depăşesc limitele perioadei analizate (tab. III). Consecința imediată este obținerea unei probabilități de eroare mai mari în specificarea intervalului ($p > 0.05$). În cazul mai multor fenotipuri se poate identifica totuşi un moment de apariție semnificativ statistic (limită inferioară ulterioară datei de debut a perioadei analizate - 04/2002) ceea ce semnifică probabilitate foarte mică ($p < 0.025$) de apariție a fenotipului corespunzător înainte de data calculată (tab. III).

În prezent, conform datelor din literatură, UTI post chirurgie cardiacă se confruntă cu emergența fenotipurilor rezistente, multirezistente până la panrezistente, mai ales pe seama BGN nefermentativi (3, 14). De Santo et al (3), în 2008 a constatat că 61,7 % dintre bacteriile Gram-negativ implicate în infecțiile nosocomiale după intervențiile pe cord au fost rezistente la antibiotice.

CONCLUZII

La Institutul de Boli Cardiovasculare din Iaşi în unitatea de terapie intensivă a clinicii de chirurgie cardiovasculară cei mai comuni agenți etiologici ai pneumoniei asociată ventilației mecanice post-chirurgie

cardiacă majoră sunt, în ordine descrescătoare, *Pseudomonas aeruginosa*, *Acinetobacter baumannii*, *Stenotrophomonas maltophilia* şi *Candida albicans*. Unitatea de terapie intensivă s-a confruntat după 14.06.2005 cu creşterea prevalenței fenotipurilor bacteriene multirezistente şi emergența speciilor cu rezistență intrinsecă la numeroase antibiotice. Prin utilizarea pe scară largă a antibioticelor UTI este placa turnantă pentru emergența, amplificarea şi răspândirea patogenilor rezistenți la antibiotice. Apare necesar un efort multidisciplinar de a limita acest fenomen prin supravegherea igienizării activităților cotidiene, procedurilor aseptice şi îngrijirii pacienților, dar şi printr-o țintire şi utilizare judicioasă a antibioticoterapiei.

THE ROLE OF UPPER GASTROINTESTINAL ENDOSCOPY IN EVALUATION OF PORTAL HYPERTENSION (Abstract): Portal hypertension is the main cause of complications of hepatic diseases determining portosystemic collateral circulation, ascites and gastroesophageal varices. **Aim** of the study is to review current opinions and to correlate clinical and endoscopic signs determined by portal hypertension. **Material and methods:** We performed a retrospective study on 150 patients diagnosed and treated for diseases associated with portal hypertension at the Institute of Hepatology and Gastroenterology from Iasi between 2007 and 2009. **Results and discussion:** Most of the patients presented cirrhosis (112 cases) mainly of toxic (63 cases) and viral (31 cases) etiology. In order to appreciate bleeding from esophageal varices we applied Forrest criteria and identified type Ia bleeding in 26,6% of cases and type Ib bleeding at 73,4% of patients. In 15% of cases, variceal bleeding represented the first symptom of slowly progressing hepatic cirrhosis. **Conclusions:** The objective of subsequent evaluation of small varices is detecting size increase, an important prognostic and therapeutic index. **Key words:** PORTAL HYPERTENSION, ESOPHAGEAL VARICES, UPPER GASTROINTESTINAL TRACT ENDOSCOPY.

Endoscopia constituie cea mai sensibilă metodă de identificare şi clasificare în funcţie de risc a dilataţiilor varicoase, motiv pentru care se constituie şi într-o procedură de elecţie în diagnosticul şi tratamentul statusului variceal asociat HTP. Diagnosticul endoscopic al varicelor esofagiene se constituie într-un factor de prognostic relevant în ceea ce priveşte riscul predictiv individual de hemoragie, corelat direct cu gradul de dilatare şi diametrul varicelor esofagiene, gastropatia portală, apartenenţa la clasa Child (1, 2).Scopul acestui studiu este a trece în revistă opiniile moderne cu privire la complicaţiile hipertensiunii portale şi de a analiza comparativ aspectele clinice şi endoscopice evidenţiate la pacienţii cu hipertensiune portală.

MATERIAL ŞI METODĂ

Cercetarea de faţă realizează un studiu retrospectiv comparativ pe o perioadă de 3 ani, cuprinsă între 2007 şi 2009 pe un număr de 150 pacienţi diagnosticaţi, investigaţi endoscopic şi trataţi în cadrul Institutului de Gastroenterologie şi Hepatologie pentru complicaţii asociate hipertensiunii portale.

Baza de date a studiului de faţă a fost realizată folosind informaţiile obţinute din foile de observaţie clinică ale pacienţilor selectaţi şi înregistrările din protocoalele investigaţiilor endoscopice. Datele obţinute au fost analizate şi exprimate procentual, iar asocierile dintre diferiţi factori, au fost interpretate cu ajutorul testelor de corelaţie. Prelucrarea statistică a fost realizată prin intermediul programului Statistica 8.0.

Criteriile de includere a pacienţilor în loturile de studiu au asociat date de identificare (vârstă, sex, mediu de proveniență, durata spitalizării, traseul interclinic), motivele internării, diagnosticul de internare; comorbidităţi, antecedente medicale şi chirurgicale.

Criteriile de excludere a pacienţilor din lotul de studiu au asociat pacienţi care au refuzat indicaţia diagnostică sau includerea în lotul de studiu, pacienţi cu vârsta sub 16 ani.

REZULTATE

Din cei 150 de pacienţi incluşi în studiu, 106 au fost de sex masculin, iar 44 de sex feminin. Vârsta medie a pacienţilor cuprinşi în lot a fost de 54,32±9,70 ani, cu valori extreme de 34 şi 68 de ani. Majoritatea pacienţilor (112 cazuri) au prezentat afectare hepatică de tip cirotic, predominant de etiologie toxică (63 de pacienţi), urmată de etiologia virală (31 de pacienţi), intricarea celor două mecanisme etiopatogenice fiind identificată în 18 de cazuri.

Prognosticul pacienţilor conform clasificării Child este redat în tabelul I.

Varice esofagiene de diferite grade au fost decelate în cazul a 65,5% pacienţi de sex masculin şi a 78,3% pacienţi de sex feminin (tab. II). Varice gastrice au fost observate numai în cazul pacienţilor de sex masculin (6,2%).

TABELUL I

Încadrarea pacienţilor din lot în clasificarea Child

	Masculin	**Feminin**
Child A	41,5%	43,18%
Child B	45,28%	47,72%
Child C	13,22%	9,1%

TABELUL II

Clasificarea pacienţilor în funcţie de severitatea varicelor esofagiene

Varice absente	29,28%
Varice gradul I	13,81%
Varice gradul II	25,66%
Varice gradul III	31,25%

Hemoragia digestivă superioară (HDS) a fost prezentă în antecedentele a 33,6% pacienţi de sex masculin şi a 35,1% pacienţi de sex feminin. HDS, uşoară în majoritatea cazurilor, exteriorizată sub formă de hematemeză şi melenă de peste 60% dintre pacienţi.

Cei mai mulţi dintre pacienţi (46,7%) nu au primit tratament HDS anterior internării curente, iar beta-blocantele, selective şi neselective, au reprezentat terapia de elecţie (tab. III) în majoritatea situaţiilor.

TABELUL III

Tratamentul de prevenire al HDS în lotul studiat

Măsura terapeutică	
Beta-blocante neselective	25,98%
Beta-blocante + nitraţi	6,9%
Beta-blocante + IPP	14,8%
Beta-blocante + nitraţi + IPP	2,3%
Nitraţi	3,32%
Fără tratament	46,7%

Endoscopia digestivă superioară (EDS) s-a efectuat prin folosirea unui fibroscop de

tip Olympus GIF tip XQ20, dotat cu o înaltă flexibilitate şi elasticitate. Varicele esofagiene au fost diagnosticate la aproximativ 40% din pacienţii compensaţi şi la 60% din cei care prezintă ascita ca simptom principal în momentul stabilirii diagnosticului de ciroză. Evaluarea endoscopică a varicelor esofagiene s-a efectuat în funcţie de clasificarea Sarin (tab. IV)

În 15% din cazuri, hemoragia variceală a fost prima manifestare clinică a cirozei hepatice cu evoluţie latentă.

TABELUL IV

Repartiţia pacienţilor examinaţi endoscopic în funcţie de severitatea varicelor esofagiene

Varice izolate	42%
Varice tip I	16,67%
Varice tip IIa	22,67%
Varice tip IIb	11,33%
Varice tip III	7,33%

În vederea aprecierii activităţii hemoragiilor variceale au fost aplicate criteriile Forrest, identificându-se hemoragie în jet (Forrest Ia) la 26,6% din pacienţi, iar hemoragie Forrest Ib la 73,4% din cazuri (fig. 1).

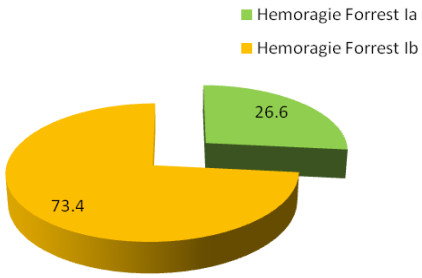

Fig. 1. Repartiţia pacienţilor în funcţie de severitatea hemoragiei variceale

DISCUŢII

Incidenţa varicelor esofagiene la pacienţii cirotici se estimează a fi de 5% pe an, motiv pentru care tendinţa actuală este de a practica endoscopia ca metodă de screening la toţi pacienţii cu suspiciune de HTP. La pacienţii care nu prezintă varice la endoscopia iniţială, trebuie efectuată o evaluare secundară în vederea identificării dezvoltării varicelor înainte ca acestea să sângereze, consensul general fiind de a practica o a două endoscopie după 2-3 ani la toţi aceşti pacienţi. La pacienţii care prezintă varice mici la endoscopia iniţială, obiectivul evaluărilor subsecvente îl constituie detectarea progresiei de la varice mici la varice mari, ca mijloc important de prognostic şi terapie (3, 4).

Rata de progresie a dimensiunilor varicelor este de 10-15% pe an, motiv pentru care se consideră că endoscopia trebuie repetată la fiecare 1-2 ani la pacienţii care prezintă varice mici la examenul iniţial. În vederea interpretării corecte a rezultatelor studiilor clinice este utilă standardizarea aspectului endoscopic al varicelor (evaluarea prezenţei şi a dimensiunilor în plenitudine completă înaintea îndepărtării endoscopului) şi obţinerea de imagini digitale care pot fi revăzute şi comparate cu cele din literatura de specialitate. De asemenea, este foarte importantă ameliorarea acceptabilităţii procedurii prin realizarea unei sedări corecte cu droguri care nu modifică semnificativ HTP (5, 6).

Endoscopia evaluează caracteristicile varicelor gastroesofagiene, caracteristici extrem de importante prin valoarea lor prognostică în ceea ce priveşte hemoragia.

Ambii factori descrişi anterior şi gradul afectării hepatice sunt cuantificaţi în clasa Child-Pugh, şi constituie cel mai utilizat index prognostic al sângerărilor variceale (6) (tab. V).

Din punct de vedere practic, pacienţii cu varice esofagiene peste 5 mm în diametru prezintă risc major de sângerare variceală, mai ales dacă sunt încadraţi în clasele B sau C.

TABELUL V
Clasificarea Child-Pugh a bolilor hepatice cronice

Parametru	1 punct	2 puncte	3 puncte	Unitate de măsură
Bilirubina totală	<34 (<2)	34-50 (2-3)	>50 (>3)	μmol/l (mg/dl)
Albumina serică	>35	28-35	<28	g/l
INR	<1.7	1.71-2.20	>2.2	-
Ascită	Absent	Reversibilă medicamentos	Refractară	-
Encefalopatie portală	Absent	Gradele I-II (sau reversibilă medicamentos)	Gradele III-IV (sau refractară)	-

Puncte	Clasa	Supraviețuire la 1 an	Supraviețuire la 2 ani
5-6	A	100%	85%
7-9	B	81%	57%
10-15	C	45%	35%

Identificarea varicelor gastrice la endoscopie poate fi realizată cu unele dificultăți tehnice care, momentan, au fost depăşite prin introducerea endosonografiei. Astfel, se pot identifica varicele gastrice ca fiind structuri anecogene, rotunde, localizate majoritar în submucoasa gastrică. Recent a fost introdus un indice endoscopic care combină dimensiunea varicelor cu prezența gastropatiei hipertensive portale şi a varicelor gastrice. Valoarea sa în evaluarea HTP rămâne încă discutabilă.

CONCLUZII

Datorită mortalității crescute a varicelor esofagiene este importantă efectuarea endoscopiei la fiecare pacient cu HTP. Prezența varicelor gastroesofagiene confirmă diagnosticul deşi absența lor nu exclude HTP. Există situații în care varicele esofagiene sunt diagnosticate incidental în cazul unor pacienți la care se practică endoscopie pentru alte afecțiuni gastroesofagiene, situație în care etiologia HTP trebuie imediat identificată. În vederea interpretării corecte a rezultatelor studiilor clinice este utilă standardizarea aspectului endoscopic al varicelor (evaluare prezenței şi a dimensiunilor în plenitudine completă, înaintea îndepărtării endoscopului) şi obținerea de imagini digitale care pot fi revăzute şi comparate.

Clinica I Medicală Cardiologică

CARDIORENAL SYNDROME (Abstract): Cardiac and renal disease are common and frequently coexist, resulting in increased risk of mortality, morbidity and cost of care. The interaction between heart and kidney is refered to as cardiorenal syndrome, but a consensus definition has not been established. Also, there are limited data about the true incidence, the pathophisiology is poorly understood and standardized diagnostic criteria are lacking. Because the process is complex, treatment can be a challenge despite the novel therapies. This paper addresses all the complex interactive aspects of the cardiorenal relationship, from pathophysiology to epidemiology, diagnosis and treatment, to have more clear perspectives on the future therapeutic approaches to this deadly association. **Key words**: CARDIORENAL SYNDROME, HEART FAILURE, RENAL DYSFUNCTION, DIURETICS, DIURETIC RESISTANCE.

IMPORTANŢA PROBLEMEI: PREVALENŢA REALĂ NECUNOSCUTĂ

Relaţia între boala renală cronică (BRC) şi insuficienţa cardiacă (IC) este dovedită de numeroase trialuri şi studii clinice. Relaţia este bidirecţională, se manifestă din stadii precoce de afectare a unuia din cele două organe şi are impact asupra prognosticului cardiovascular.

Incidenţa afectării cardiorenale are un trend ascendent evident din cauza creşterii ponderii populaţiei vârstnice, a hipertensiunii arteriale, diabetului zaharat, obezităţii şi altor factori de risc cardiovascular. Primele date epidemiologice consistente sunt oferite de trialul Acute Decompensated Heart Failure National Registry (ADHERE) care a înrolat 105.388 de pacienţi neselecţionaţi spitalizaţi pentru IC acută (1). Trialul raportează că 1 din 3 pacienţi au diagnostic concomitent de BRC. Metaanaliza lui Smith confirmă frecvenţa crescută a afectării renale în IC (63% din pacienţi, dintre care 20% cu afectare moderată şi severă) precum şi relaţia cu severitatea IC (clearence de creatinină < 30 ml/min la 39% din cazurile de IC clasa NYHA IV şi 31% din cazurile de IC clasa NYHA III) (2). Interesant este că BRC este prezentă în egală măsură în IC cu fracţie de ejecţie scăzută sau păstrată (2, 3, 4).

Studiile ulterioare atrag atenţia asupra *semnificaţiei prognostice a BRC la pacientul cu IC*. Deteriorarea funcţiei renale se produce la 27-45% din cazurile de IC acută, în general în faza iniţială a spitalizării. La aceste categorii de pacienţi o creştere cu 0,3 mg % a creatininei determină o creştere a duratei spitalizării şi a mor-

talităţii pe termen scurt şi lung (5). Trialul ESCAPE subliniază că episoadele de decompensare a IC sunt asociate frecvent cu disfuncţia renală care necesită doze crescute de diuretice (6).

Implicaţiile prognostice trebuie privite şi din perspectiva *rolului IC asupra afectării renale*. Problema este importantă atât din cauza incidenţei crescute a BRC (în SUA peste 8 milioane de indivizi au rata de filtrare glomerulară < 60 ml/min conform raportului NHANES III), cât şi a riscului asociat înalt pentru infarct miocardic, IC, mortalitate de cauză cardiovasculară (2, 7). Metaanaliza lui Tonelli arată că indivizii cu BRC primară au risc de mortalitate cardiovasculară de 10-20 de ori mai mare (8), iar IC este o prezenţă comună în stadiile avansate, atingând rate de până la 33% (9).

Problema actuală din punct de vedere epidemiologic *este uniformizarea definirii disfuncţiei renale*. Cu alte cuvinte, care este parametrul standard şi gradul de modificare necesar pentru definirea SCR? Metaanaliza lui Smith pe 16 trialuri (80.000 de pacienţi) arată că afectarea renală este definită variabil ca rată de filtrare glomerulară estimată (RFGe) < 90 ml/min, creatinină > 1 mg %, cystatin C > 1,03 mg % etc (2). Pe de altă parte, relaţia disfuncţiei renale cu riscul de morbiditate şi mortalitate prin IC este raportată diferit. De exemplu, în studiul Enhanced Feedback for Effective Cardiac Treatment (EFFECT) ureea serică şi hiponatremia sunt considerate predictori independenţi ai prognosticului cardiovascular, care contribuie la creşterea cu 20% a mortalităţii prin IC (10). Owan demonstrează că riscul de mortalitate prin IC creşte cu 15% pentru fiecare creştere cu 0,5 mg % a creatininei (3). Hillege subliniază că descreşterea cu fiecare 10 ml/min a RFGe duce la creşterea cu 7% a mortalităţii cardiovasculare (11). Aspectul este important deoarece, conform National Kidney Foundation, definirea standard a BRC se face în funcţie de valorile RFGe, parametru cu valoare dovedită de predictor independent al mortalităţii în IC (1, 12, 13) superior chiar fracţiei de ejecţie (14).

Problema rămâne deschisă dar este esenţială pentru stabilirea incidenţei reale a sindromului cardiorenal (SCR) în trialuri prospective randomizate. La ora actuală putem afirma doar că SCR este o prezenţă comună în practica clinică.

DEFINIŢIA SINDROMULUI CARDIORENAL: O EVALUARE ÎN PROGRES

Natura complexă şi insuficient clarificată a SCR nu a permis elaborarea unei definiţii universal acceptate. În 2004 grupul de lucru al National Heart, Lung, and Blood Institute defineşte SCR ca "rezultatul interacţiunii între rinichi şi alte compartimente circulatorii care cresc volumul circulant şi agravează simptomele de IC şi progresia bolii. În forma avansată terapia de ameliorare a simptomelor de IC congestivă este limitată de agravarea consecutivă a funcţiei renale" (15). Ulterior sunt propuse diverse definiţii:

- "o condiţie fiziopatologică în care disfuncţia combinată cardiacă şi renală amplifică progresia insuficienţei fiecăruia din organe şi conduce la creşterea morbi-mortalităţii" (16)
- "prezenţa sau dezvoltarea disfuncţiei renale la pacientul cu IC" (17)
- "sindromul în care cordul sau rinichiul nu poate compensa disfuncţia celuilalt organ, ducând la un cerc vicios care determină decompensarea întregului sistem cardiocirculator" (18).

Toate definiţiile sunt considerate în prezent "prea simpliste pentru a fi exacte" deoarece reflectă prin enunţuri succinte modalitatea comună de utilizare a termenului, care pune în centrul problemei IC (19). La Congresul Mondial de Nefrologie din 2008, Ronco şi colab. propun o nouă definiţie a SCR. Autorii utilizează termenul de *sindroame cardiorenale* şi subliniază două aspecte: injuria primară poate fi cardiacă sau renală şi poate avea caracter acut sau cronic. Conform acestui concept, SCR este "dezordinea fiziopatologică a cordului şi rinichiului în care disfuncţia acută sau cronică a unui organ poate induce disfuncţia acută sau cronică a celuilalt organ" (20). Pornind de la o amplă analiză a secvenţei mecanismelor fiziopatologice implicate definiţia este completată cu o *clasificare* inovatoare şi foarte practică *în 5 tipuri* (21) (tab. I). Definiţia necesită câteva precizări (21):

- tipul 3 este incomplet caracterizat deoarece definirea uniformă a insuficienţei renale acute este introdusă recent în studii (criteriile RIFLE). În această categorie pot fi incluşi pacienţii cu stenoză bilaterală de arteră renală, cei din secţiile de cardio-chirurgie în perioada postoperatorie sau supuşi unei explorări angiografice cu substanţă de contrast.
- tipul 5, deşi nu se caracterizează prin afectare primară cardiacă sau renală, este inclus în SCR. Afecţiunile sistemice care conduc la injuria şi/sau disfuncţia simultană a celor două organe acţionează prin mecanisme comune în SCR şi anume stres oxidativ, inflamaţie, disfuncţie endotelială, activare neuroumorală.

TABELUL I

Clasificarea sindroamelor cardiorenale

Tip	Denumire	Mecanism	Condiţii clinice
1	Sdr. cardiorenal acut (27-40% în IC acută)	Agravarea bruscă a funcţiei cardiace determină insuficienţă renală acută	Şoc cardiogen, IC decompensată acut, sindrom coronarian acut
2	Sdr. cardiorenal cronic (63% în IC congestivă)	Insuficienţa cardiacă cronică determină afectare progresivă a funcţiei renale	IC cronică congestivă
3	Sdr. renocardiac acut	Agravarea bruscă a funcţiei renale determină insuficienţă cardiacă acută (frecvent edem pulmonar acut)	Insuficienţă renală acută prin ischemie renală acută, glomerulonefrite, stenoză bilaterală de arteră renală, nefropatie de contrast
4	Sdr. renocardiac cronic	Insuficienţa renală cronică contribuie la declinul funcţiei cardiace	Nefropatii glomerulare sau interstiţiale cronice
5	Sdr. cardiorenal secundar	Condiţie sistemică ce determină disfuncţie cardiacă şi renală concomitentă	Diabet zaharat, sepsis, lupus eritematos sistemic, amiloidoză, afecţiuni cronice inflamatorii

- sistemul de clasificare este considerat perfectibil deoarece mulţi pacienţi pot popula sau pot migra între diferite tipuri în cursul evoluţiei afecţiunii. Grupul de lucru ADQI opinează pentru îmbunătăţirea clasificării cu noi subtipuri ca situaţiile de disfuncţie reversibilă sau tranzitorie, afectarea rapid progresivă, boala stabilă etc.
- există deja opinia formulată de unii autori că tipurile 2 şi 4 ar trebui unificate, deoarece distincţia în practică nu este întotdeauna posibilă iar terapia nu este semnificativ diferită (22).

Indiferent de opinie, există consens că scopul final în definirea articulată a SCR rămâne facilitarea studiilor epidemiologice prospective cu design clar şi omogen, care să permită medicului practician identificarea populaţiilor ţintă pentru intervenţia terapeutică, diagnosticul după criterii standardizate, prevenţia şi tratamentul adecvat.

FIZIOPATOLOGIA: ÎNCĂ O NECUNOSCUTĂ

SCR este considerat mai mult decât o afectare simultană cardiacă şi renală. Factorii patogenici implicaţi (hipertensiunea arterială, diabetul zaharat, obezitatea, boala coronariană etc.) reprezintă precursori comuni ai IC şi BRC. Pacienţii cu SCR convieţuiesc cu un mediu fragil, dominat de modificări hemodinamice, neuro-umorale dar şi de mulţi alţi factori incomplet descifraţi şi clarificaţi (23).

Există totuşi câteva ipoteze cristalizate (24, 25):

1. ***teoria hemodinamică*** este explicată în mod tradiţional prin *mecanismul hipovolemic*. Declinul RFGe în IC reflectă perfuzia inadecvată renală secundară scăderii debitului cardiac, adică apare insuficienţa renală funcţională prin mecanism prerenal. Rezultă eliberare de renină şi activarea sistemului renină-angiotensină-aldosteron (SRRA) care determină retenţie hidro-salină, constricţia arteriolei aferente şi scăderea perfuziei glomerulare, stimulare neuro-umorală cu activitate proinflamatorie, proliferativă, profibrotică. Se discută şi eliberarea unui "factor depresor miocardic" care afectează suplimentar debitul cardiac (Blake şi colab. cit. de 26). Mecanismul este corect dar explică parţial evoluţia pacienţilor cu SCR. De asemenea nu s-a dovedit o relaţie evidentă şi constantă între evoluţia funcţiei cardiace şi renale pe termen scurt şi lung (24). La ora actuală este susţinută *teoria hipervolemică*, o reactualizare a modelului experimental descris de Watkins în 1931. Conceptul central este *congestia venoasă*, iar termenul propus în acest sens este de insuficienţă renală congestivă. Conform teoriei, creşterea presiunii venoase centrale se transmite retrograd şi determină:

a. creşterea presiunii în venele renale. Rezultă creşterea presiunii interstiţiale renale şi ischemia parenchimului renal. Concomitent, creşterea presiunii venoase într-un organ încapsulat cum este rinichiul, duce la distensia venulelor din jurul tubilor distali care pot fi obliteraţi. În ansamblu ischemia generează activare neuro-umorală cu efecte hemodinamice nocive.

b. creşterea presiunii intraabdominale ca parte a "sindromului de compartimentare abdominală". Mecanismul apare la peste 60% din cazurile avansate de IC. Rezultă un efect direct de compresiune renală dar şi de creştere a presiunii venoase centrale. Se închide un cerc vicios care compromite funcţia renală.

2. ***teoria conexiunii cardio-renale*** este o extensie a modelului Guytonian de control a volemiei şi tensiunii arteriale (TA) prin interacţiunea cord-rinichi, care iniţiază

răspunsul fiziologic numit reacţie hemodinamică defensivă (16, 27). La conceptul hemodinamic clasic, Bongartz adaugă rolul "*conectorilor cardio-renali*" reprezentaţi de balanţa improprie oxid nitric-radicali liberi de oxigen, activarea SRRA şi a sistemului nervos simpatic, inflamaţia. Când unul din organe devine insuficient conectorii interacţionează sinergic dar dezechilibrat şi întreţin deteriorarea funcţiei cardiace şi renale (19, 28).

3. ***ţintele renale potenţiale*** sunt reprezentate de factori/mecanisme clasice în IC: *sistemul arginin-vasopresină, sistemul peptidelor natriuretice*, mai nou *adenozina* cu efect negativ asupra feed-back-ului tubuloglomerular (29). Studiile clinice şi experimentale sugerează că aceste mecanisme ar produce în mod direct injurie tubulointerstiţială, independent de prezenţa sau absenţa IC. La aceste ţinte se adaugă rolul binecunoscut al deficitului de eritropoietină şi anemiei, frecvent întâlnite în SCR şi IC. Importanţa problemei este ilustrată de conceptul de *sindrom cardiorenal-anemie* sau "triada mortală" (24, 30, 31, 32) conform căruia anemia este actorul principal în inducerea inflamaţiei, stresului oxidativ şi apoptozei miocardice şi renale.

DIAGNOSTICUL ÎN PRACTICĂ: O PROBLEMĂ INCOMPLET REZOLVATĂ

Depistarea SCR presupune *identificarea factorilor de risc* pentru agravarea funcţiei renale. Profilul clinic este comun – pacient vârstnic, diabetic, hipertensiv, cu sindrom anemic, care poate avea istoric de infarct miocardic, IC sau BRC şi este sub tratament cronic cu diuretice, inhibitori ai enzimei de conversie a angiotensinei (IECA), sartani sau are tratament recent cu antiinflamatorii nesteroidiene. În mod particular prezenţa afectării renale intrinseci este unul din cei mai importanţi factori de risc pentru evoluţia spre SCR.

Pentru confirmarea diagnosticului grupul ADQI a propus o baterie largă de *biomarkeri cardiaci şi renali* utili în diferite subtipuri de SCR (21). Problema practică este specificitatea şi sensibilitatea pentru SCR, precum şi disponibilitatea, costul biomarkerilor. La ora actuală biomarkerii recomandaţi şi utilizaţi pe scară largă sunt *BNP (NT-proBNP) şi RFGe*. Alţi markeri ce necesită confirmare în studii viitoare sunt:

1. cardiaci – mieloperoxidaza, citokine (TNF-α, IL-6, IL-8, IL-18), procalcitonina; troponinele rămân utile în cazul sindroamelor coronariene acute.
2. renali:

a. de injurie renală: *NGAL* (gelatinaza neutrofilă asociată lipocalinei) – marker foarte precoce, înalt sensibil şi specific pentru afectarea ischemică sau nefrotoxică, KIM-1 (kidney injury molecule-1), N-acetil-ß-$_{(D)}$glucozaminidaza, IL-18, netrin-1, α şi γ-GST (glutation-S-transferaza), L-FABP (acizi graşi tipul L care leagă proteine) etc. Recent se discută şi rolul urotensinei II şi renalazei urinare (33, 34).

b. cystatin C (seric şi urinar) – marker cu nivel de predicţie superioară asupra funcţiei glomerulare respectiv tubulare, comparativ cu creatinina serică.

NGAL urinar şi plasmatic, cystatin C sunt biomarkerii cu şansele cele mai mari de a fi integraţi în practica clinică în viitorul apropiat.

Optimizarea supravegherii în SCR înseamnă monitorizarea:

1. funcţiei renale prin RFGe în mod obligatoriu. Scăderea cu 9-15 ml/min/1,73 m^2 este suficientă pentru a atrage atenţia asupra agravării funcţiei renale. Modificarea RFGe este precoce şi mult mai sensibilă

comparativ cu creatinina serică, utilizată ca surogat al funcţiei renale. Între cei doi parametri există o relaţie exponenţială, adică o modificare minoră a creatininei reflectă reduceri semnificative ale RFGe (35, 36). Pe de altă parte, în SCR, ureea serică este un marker înalt predictiv al mortalităţii în spital (trialul ADHERE) dar şi al evoluţiei pe termen scurt şi lung (37, 38). Hiponatremia refractară în ciuda tratamentului diuretic este un alt indicator al incapacităţii renale de a compensa hipervolemia independent de debitul cardiac (26). Markerul clinic cel mai sensibil pentru urmărire rămâne măsurarea greutăţii (39). În insuficienţa renală acută se impune pentru standardizare utilizarea criteriilor RIFLE (21).

2. cordului prin investigare seriată ecocardiografică, ce oferă posibilitatea evaluării neinvazive hemodinamice precise. Metoda rămâne standardul de aur, în timp ce monitorizarea invazivă a presiunii venoase centrale şi pulmonare capilare blocate rămâne controversată sau cel puţin limitată la anumite categorii de pacienţi (40). Grupul consens ADQI remarcă utilitatea unei metode deja disponibile – analiza vectorului de bioimpedanţă în monitorizarea şi managementul stării de hidratare (21).

TRATAMENTUL: O PROVOCARE MAJORĂ

Sarcina de a trata pacientul cu SCR este dificilă din mai multe motive: nu există dovezi epidemiologice consistente întrucât majoritatea trialurilor exclud disfuncţia renală, tratamentul este în general adresat IC în timp ce urmărirea funcţiei renale trece pe un plan secundar, nu există o terapie eficientă pentru toate categoriile de pacienţi. Terapia actuală este mai degrabă empirică decât bazată pe dovezi, iar decizia de tratament trebuie adaptată individual operând cu resursele disponibile (19). Există de *3 principii majore* ale conduitei terapeutice în SCR: evitarea agravării evoluţiei pe termen scurt cu terapia preexistentă, urmărirea activă a disfuncţiei cardio-renale, utilizarea medicaţiei protectoare renale (26).

Algoritmul practic de instituire a terapiei în SCR *trebuie să răspundă la 3 întrebări* (41):

1. care este statusul volemic? În caz de hipovolemie se constată agravarea funcţiei renale indusă de terapia IC. Se impune oprirea diureticului de ansă, reducerea dozelor/oprirea medicaţiei cu IECA, sartani, spironolactonă şi umplere volemică. Hipervolemia este sugerată de persistenţa dispneei şi a retenţiei hidrosaline, agravarea funcţiei renale, presiune venoasă centrală crescută. În acest caz problema devine manipularea adecvată a diureticului de ansă. Diureticele rămân piatra de temelie a tratamentului în IC, deşi dovezile epidemiologice sunt discordante vis-à-vis de efectele benefice (42, 43). Funcţia renală este vulnerabilă la terapia diuretică, deoarece există riscul de reducere a RFGe prin mecanisme multiple (42). În ciuda efectelor favorabile pe termen scurt, trialurile atrag atenţia că la 1 din 5 pacienţi edemele nu răspund favorabil la tratament (1), iar creşterea dozelor se asociază cu exces de mortalitate (Ahmed A. cit. de 43). În practica clinică a SCR se constată frecvent că retenţia hidro-salină persistă sau se accentuează în ciuda creşterii dozelor. Situaţia este numită *rezistenţă la diuretice* şi este consecinţa creşterii pragului renal de eliminare a sodiului şi a scăderii eficienţei diureticului. Tratamentul presupune recunoaşterea cauzelor: exces de sodiu în alimentaţie, utilizarea clandestină de antiinflamatorii nesteroidiene, absorbţie scăzută

a diureticului la nivel intestinal sau doze insuficiente de diuretic, hipoalbuminemie etc (44, 45). Al doilea pas este administrarea diureticului de ansă pe cale intravenoasă. Se preferă perfuzia cu doze mari de furosemid în 30-60 de minute şi nu bolusuri repetate, eventual utilizarea altor diuretice de ansă cu absorbţie eficientă pe cale orală (torsemid, bumetanid). O manevră utilă este asocierea dozelor mici de diuretic tiazidic pentru inhibarea reabsorbţiei distale de sodiu. În caz de hipoalbuminemie se recomandă asocierea albuminei umane desodate. În prezent se testează eficienţa dozelor mari de furosemid (500-1000 mg/zi) asociate cu soluţie salină hipertonă (150 ml cu concentraţie 1,4-4,6% în funcţie de sodiul seric) administrate în 30 de minute. Mecanismele posibile ar fi mobilizarea rapidă a fluidelor extravasculare în spaţiul intravascular, de unde pot fi mai uşor eliminate, modularea activării neuroumorale şi a funcţiei renale (46). Deşi există aceste alternative, se aşteaptă elaborarea unei decizii finale în urma publicării rezultatelor trialului DOSE-AHF (47).

O terapie la competiţie cu diureticele în SCR cu hipervolemie este *ultrafiltrarea*. Metoda are la bază principiul aquaferezei, adică eliminarea de lichide izotone cu prezervarea funcţiei renale. Studiată în cadrul trialului UNLOAD, ultrafiltrarea ameliorează semnificativ retenţia hidro-salină şi rata de respitalizare, dar nu şi-a dovedit eficienţa asupra ameliorării funcţiei renale şi supravieţuirii (48). În 2009 a fost iniţiat un nou trial CARESS-HF (CARdiorenal REScue Study in Acute Decompensated Heart Failure) actualmente în desfăşurare (49).

2. cum este perfuzia renală? Aspectul impune optimizarea parametrilor hemodinamici care condiţionează funcţia renală – TA şi debitul cardiac. Primul gest terapeutic este revizuirea medicaţiei vasodilatatoare şi diuretice utilizate (IECA, sartani, betablocante, spironolactonă) cu efecte benefice indiscutabile prin blocare neuroumorală, dar care poate avea impact negativ hemodinamic şi asupra funcţiei renale. În IC acută gestul terapeutic încetăţenit este administrarea agenţilor inotropi pozitivi sau a vasodilatatoarelor injectabile (nitroglicerină, nitroprusiat, nesiritide) după caz. Ca şi în cazul diureticelor există însă numeroase dovezi epidemiologice (trialurile OPTIME, SURVIVE, metaanalize referitoare la dopamină şi nesiritide) care sugerează efectul nefavorabil asupra funcţiei renale şi supravieţuirii pentru toate tipurile de medicaţie (50, 51, 52). În SCR atenţia se îndreaptă în continuare asupra dopaminei în doze mici de 2 γ/kg/min, strategie explorată în cadrul trialului ROSE-AHF (53). În ce priveşte nesiritide există câteva trialuri cu design comun care sprijină efectul benefic asupra funcţiei renale în cazul utilizării dozelor mici, fără efect asupra TA (54, Hebeler cit. de 26, Riter cit. 41). Verdictul va fi dat probabil de trialul ASCEND-HF la finele anului 2010 (55).

3. există afectare renală intrinsecă? În paralel cu asigurarea statusului de euvolemie şi optimizarea perfuziei renale, atenţia trebuie dirijată spre evaluarea cauzei afectării renale şi a factorilor precipitanţi. Afectarea renală intrinsecă trebuie suspectată dacă disfuncţia renală persistă după corecţie hemodinamică, situaţie întâlnită în mod tipic în diabetul zaharat, hipertensiunea arterială sau afectarea renovasculară.

Strategii de viitor în tratamentul SCR (23, 24, 26, 43, 50)

Interesul pentru managementul adecvat, centrat pe terapia protectoare renală, este susţinut de testarea noilor strategii cu clase

terapeutice deja cunoscute sau nestudiate până în prezent:

- *antagoniştii de vasopresină* (vaptani) sunt cunoscuţi din trialuri finalizate (ADVANCE, ACTIV, EVEREST etc.) ca medicaţie utilă în manipularea rezistenţei la diuretice fără a induce tulburări electrolitice, dar fără efect pe mortalitate sau de ameliorare a funcţiei renale. Rămâne de evaluat eficienţa şi superioritatea lor în comparaţie cu ultrafiltrarea.
- *antagoniştii de receptori de adenozină* A_1 sunt o ţintă terapeutică de studiu în IC acută şi cronică, pornindu-se de la rezultatele favorabile asupra diurezei, natriurezei şi funcţiei renale promovate de trialurile PROTECT-1 şi 2, TRIDENT, REACH-UP. Trialul PROTECT-III recent publicat nu confirmă efectele favorabile cardiace şi asupra funcţiei renale cu rolofylline (56). Rezultatele nu exclud această clasă terapeutică, un rol potenţial fiind prevenţia nefropatiei de contrast şi a rezistenţei la diuretice, sau în caz de hipotensiune (50).
- *peptidul natriuretic sintetic CD-NP* este o ţintă nouă investigată în trialul CONDITION-HF (57). CD-NP este un peptid chimeric inovator testat în studii experimentale, care are avantajul combinării efectelor favorabile ale peptidului C (antiproliferativ, venodilatator cu efect minim hipotensor) şi D (diuretic, natriuretic).
- *activatorii solubili de guanilat-cyclază* (BAY 58-2667 cinaciguat, HMR1766 atisciguat) au fost testaţi cu succes în studii experimentale. Mecanismul de acţiune este de inducere a vasodilataţiei via oxid nitric, iar la nivel renal creşterea excreţiei de sodiu cu prezervarea filtrării glomerulare.
- *darbepoetin alfa* este testat în trialul în desfăşurare RED-HF ca urmare a rezultatelor preliminare conform cărora utilizarea regulată de eritropoietină la pacienţii anemici cu disfuncţie renală ameliorează performanţa cardiacă şi întârzie progresia afectării renale. Nu este clar asupra căruia dintre conectorii cardio-renali acţionează predominant eritropoietina.
- *alte terapii de prezervare a funcţiei renale* în studiu sunt eliberarea dirijată intrarenală arterială pe cateter a medicaţiei sau extinderea indicaţiilor de utilizare a dispozitivelor de asistare mecanică ventriculară (INTERMACS Registry) (59).

CONCLUZIE

Mesajul cheie este că dezvoltarea sindromului cardiorenal este o etapă evolutivă dezastruoasă în istoria naturală a IC sau a BRC care trebuie depistată în mod activ şi precoce. În ciuda terapiilor inovatoare care se prefigurează, managementul adecvat este în impas, de aceea prevenţia şi optimizarea strategiilor existente rămân deocamdată cheia succesului.

CHRONIC HEPATITIS C, STEATOSIS AND INSULIN RESISTANCE – CLINICAL IMPLICATIONS (Abstract): Chronic infection with hepatitis C virus is nowadays responsible for many cases of liver disease. According to recent research, it seems to be characterized by a great deal of metabolic abnormalities, most of them due to insulin resistance, which is present in the virus C-induced disease more often than in chronic hepatitis B or in the general population. As insulin resistance significantly impairs the natural course of the viral disease by reducing the efficacy of antiviral treatment and aggravating the development of fibrosis, it becomes more and more plausible that therapeutic intervention aiming to reduce it might contribute to a better course in many patients. Hepatic steatosis is also a frequent feature of chronic hepatitis C, being either induced by the infection with genotype 3 or by a predisposing metabolic background. The relation between steatosis and viral disease prognosis is controversial, probably due to the various factors inducing lipid accumulation. A better understanding of the metabolic substrate of chronic hepatitis C would help developing new approaches in its diagnosis and therapy, hopefully providing a better future to many patients. **Key words:** CHRONIC HEPATITIS C, INSULIN RESISTANCE, STEATOSIS, FIBROSIS

Medicina ultimilor ani conține variate exemple de descoperiri ştiințifice care îi induc un caracter interdisciplinar. Unul dintre aceste cazuri este conexiunea care a fost descoperită între diverse boli hepatice şi mecanismele de natură dismetabolică ce par a sta într-o mare măsură la baza acestora. Pe lângă steatohepatita nonalcoolică, o entitate clinică recent descrisă, dar care este deja considerată de mulți autori drept cea mai frecventă afecțiune hepatică în epoca contemporană, există numeroase dovezi că hepatita cronică cu virus C – o altă patologie de mare impact pe plan mondial la ora actuală – se caracterizează prin numeroase verigi fiziopatologice care o transformă măcar parțial într-o maladie metabolică, ce evoluează pe fondul unei rezistențe crescute la acțiunea insulinei şi a acumulării intrahepatocitare de lipide. Se speră chiar că în următorii ani, pe măsură ce aceste mecanisme patogenice vor fi înțelese, vor fi posibile adaptarea şi eventual completarea mijloacelor actuale de tratament antiviral în scopul creşterii eficienței terapeutice.

INSULINOREZISTENŢA ŞI HEPATITA CU VIRUS C

În ultimii douăzeci de ani s-au adunat treptat dovezi care leagă hepatita cronică cu virus C de un risc crescut de apariţie a insulinorezistenţei şi chiar a diabetului zaharat tip 2 (1).

Ciroza hepatică, indiferent de etiologie, se asociază cu perturbări ale metabolismului glucidic, printre care insulinorezistenţa, hiperinsulinismul şi uneori hiperglicemia (1). Prevalenţa diabetului zaharat este însă deosebit de ridicată, între 24 şi 50%, la pacienţii cu ciroză hepatică indusă de infecţia cu virus hepatitic C (2), adică de 3-5 ori mai mare decât la persoanele cu ciroză hepatică de altă etiologie, inclusiv cea datorată hepatitei cronice cu virus B (3).

Mai mult decât atât, diabetul zaharat este de 2-4 ori mai frecvent întâlnit la pacienţii non-cirotici cu infecţie virală C decât la persoanele cu hepatite cronice de altă etiologie, diverşi cercetători raportând o prevalenţă a diabetului zaharat situată între 7,6% şi 21% (3).

Pe de altă parte, comparativ cu populaţia generală, persoanele diabetice au un risc crescut de infecţie cu virusul hepatitic C, ceea ce se traduce prin existenţa markerilor serologici specifici acesteia la 4,2-10,5% dintre pacienţii cu diabet zaharat (3). Această constatare ar putea avea două explicaţii:

- susceptibilitate mai mare a diabeticilor la infecţia cu virus hepatitic C, datorată numărului crescut de spitalizări şi de manevre medicale invazive care le sunt necesare;
- inducerea hiperglicemiei de către virusul C.

Unele cercetări ştiinţifice par să dovedească fie că ARN-ul viral este prezent în ţesutul pancreatic, ceea ce ar putea determina un efect citopatic direct, fie că pacienţii cu hepatită cronică C manifestă un grad de disfuncţie β-celulară tradus prin alterarea răspunsului insulinosecretor la hiperglicemie. Ipoteza cea mai acceptată în ultimii ani de către lumea medicală este însă că efectul diabetogen al virusului hepatitic C se explică prin inducerea de către acesta a rezistenţei la insulină.

Pacienţii cu hepatită cronică C au un risc de 3 ori mai mare de apariţie a insulinorezistenţei şi a tulburărilor metabolismului glucidic. S-au raportat asocieri între severitatea rezistenţei la insulină şi mărimea încărcăturii virale (4). Insulinorezistenţa este adesea observată încă din stadii precoce ale leziunilor histologice hepatice (stadiile de fibroză 0 sau 1) (5) şi prezintă niveluri mai ridicate odată cu agravarea fibrozei şi independent de steatoză, ceea ce poate sugera că este unul dintre factorii determinanţi în progresia bolii hepatice (6). Se pare că hiperinsulinismul determinat de creşterea rezistenţei la insulină determină pe de o parte activarea directă a celulelor stelate, iar pe de altă parte induce – împreună cu eventuala hiperglicemie coexistentă – creşterea concentraţiei de CTGF (Connective Tissue Growth Factor), una din citokinele cu rol central în procesele de fibrogeneză. Interesant este faptul că unele publicaţii au sugerat că insulinorezistenţa asociată hepatitei cronice cu virus C are sediu predominant periferic (muscular) şi într-o mai mică măsură hepatic (7).

În unele studii s-a remarcat ameliorarea insulinorezistenţei la persoanele cu răspuns virusologic susţinut la tratamentul antiviral, respectiv lipsa acestor modificări la pacienţii *non-responderi* (8,9). Pe de altă parte, se pare că rezistenţa la insulină poate reduce de 2 până la 6,5 ori eficienţa tratamentului antiviral standard cu peginterferon-α şi ribavirină (10), începând să fie considerată un factor predictiv independent pentru obţine-

rea răspunsului virusologic precoce şi susţinut (10,11,12). Spre exemplu, atunci când s-a urmărit efectul terapeutic la persoanele obeze – ştiut fiind că excesul ponderal generează o rezistenţă crescută la insulină – s-a observat că pacienţii cu un IMC mai mare de 30 kg/m^2 au şanse de 4 ori mai mici de atingere a răspunsului virusologic susţinut. S-a propus chiar ca, în funcţie de nivelul insulinorezistenţei determinat prin HOMA-IR, să se opteze în viitor pentru regimuri diferite de tratament (13).

O serie de date din literatură atestă existenţa unor diferenţe în gradul de rezistenţă la insulină în funcţie de genotipul viral implicat: unii cercetători au identificat un nivel crescut al acesteia la pacienţii infectaţi cu genotipurile 1 şi 4 comparativ cu genotipul 3, iar alţii la genotipul 2a comparativ cu genotipul 1; există însă şi studii care nu au reuşit să demonstreze existenţa nici unei asocieri între insulinorezistenţă şi genotipul viral (5).

Sunt citate trei posibile mecanisme prin care virusul C induce insulinorezistenţă:

a. infecţia cu virus C determină încă din stadii precoce *creşterea nivelurilor serice ale interleukinei-6 şi TNF-α* (*Tumor Necrosis Factor-α*). Interleukina-6 inhibă autofosforilarea receptorilor insulinici hepatici şi fosforilarea IRS-1 şi IRS-2 (*Insulin Receptor Substrate-1/2*), cu un efect de scădere a sensibilităţii la insulină dovedit în unele studii experimentale. TNF-α creşte rezistenţa la insulină prin inhibarea receptorului insulinic, tirozinfosforilarea IRS-1 şi hipofosforilarea IRS-2, ceea ce alterează transmiterea semnalului postreceptor care determină mobilizarea GLUT-4 către suprafaţa membranei celulare, preluarea glucozei din mediul extracelular şi transportul transmembranar al acesteia (14);

b. virusul C determină *degradarea proteosomală a IRS-1* prin mecanisme moleculare genotip-specifice (15):

- genotipul 1 induce expresia SOCS-3 (*Suppressor of Cytokine Signaling-3*), iar genotipul 3 – expresia SOCS-7 (*Suppressor of Cytokine Signaling-7*); aceştia sunt inhibitori ai semnalului insulinic care acţionează prin ubiquitinarea IRS-1, ceea ce duce la preluarea lui intraprotosomală şi la distrugerea acestuia;
- genotipul 1b mai acţionează suplimentar şi prin activarea mTOR (*Mammalian Target of Rapamycin*), care determină serintreoninfosforilarea, redistribuţia intracelulară şi degradarea proteosomală a IRS-1;
- genotipul 3 induce şi inhibarea PPAR-γ (*Peroxisome Proliferator Activated Receptor-γ*), care implică de asemenea creşterea rezistenţei la insulină;

c. virusul C induce expresia *proteinfosfatazei 2A* printr-o cale care implică răspunsul stresor al reticulului endoplasmic; la rândul său, aceasta va defosforila o altă enzimă cheie din calea de transmitere intracelulară a semnalului insulinic, proteinkinaza B – PKB/Akt, transformând-o în varianta cu activitate kinazică scăzută (16); proteinfosfataza 2A modifică şi starea de fosforilare a AMP-kinazei, o altă enzimă cheie în homeostazia celulară energetică şi care este implicată în calea metabolică a gluconeogenezei (16).

STEATOZA HEPATICĂ ÎN INFECŢIA CU VIRUS C

Pacienţii cu hepatită cronică cu virus C prezintă steatoză hepatică în proporţie de 40-80%; cifrele variază în funcţie de coexistenţa altor factori cu potenţial de inducere a acesteia (consum de alcool, obezitate, diabet zaharat, medicaţii asociate etc.) (17). Chiar şi după excluderea influenţei exercitate de aceştia, prevalenţa

steatozei în infecţia cronică cu virus C rămâne de aproximativ 50%, mult mai mare decât cea citată în populaţia generală (circa 20%) sau la persoanele cu hepatită cronică virală B (18%) (18). La o treime dintre persoanele cu hepatită cronică C şi steatoză hepatică nu sunt prezente nici una dintre patologiile metabolice care favorizează în mod obişnuit acumularea lipidică intracelulară. Aceste constatări au determinat chiar pe unii autori să folosească – prin analogie cu NASH (*Nonalcoholic Steatohepatitis*) – termenul de VASH (*Virus-Associated Steatohepatitis*) pentru a denumi steatoza hepatică asociată infecţiei cu virus hepatitic C (1).

Efectul steatogen al virusului C este explicat de faptul că acesta utilizează mecanismele metabolismului lipidic intrahepatocitar pentru a se reproduce şi a intra în componenţa particulelor lipoproteice care se răspândesc apoi în circulaţia generală şi în întreg organismul (19), după cum se va vedea ulterior. Se pare că în membrana picăturilor lipidice care apar în citoplasma hepatocitelor secundar infectării cu virusul C se localizează întreg complexul de replicare virală, ca urmare a semnalului indus de proteina *core*, iar proteinele nonstructurale virale sunt şi ele localizate în imediata vecinătate a acestor incluzii lipidice (20).

Steatoza hepatică este mai frecventă la persoanele infectate cu genotipul viral 3a (74% faţă de 50% la alte genotipuri) (17). La acest grup de pacienţi gradul steatozei nu se corelează însă cu valoarea indicelui de masă corporală şi nici cu indicii de insulinorezistenţă, ceea ce ar putea sugera că secvenţele genotipului viral respectiv au acţiune steatogenă printr-un efect citopatic direct. Infecţia cu genotipul 3 induce dealtfel o încărcare grasă a hepatocitelor predominant în zona periportală şi nu în zona centrolobulară, ca în cazul steatozei induse de factorii metabolici. În plus, steatoza genotip 3-indusă se corelează cu replicarea şi încărcătura virală (17), nu se corelează cu progresia fibrozei (21), retrocedează în cazul succesului tratamentului antiviral şi reapare după o eventuală reinfecţie.

Potenţialul steatogen crescut al genotipului 3 se explică prin datele provenite din studii experimentale, care arată că picăturile lipidice intracitoplasmatice se formează ca urmare a unei acţiuni mai intense a proteinei sale *core*; aceasta a fost identificată chiar în membrana acestor vezicule lipidice (22). Se pare că prezenţa unui reziduu de fenilalanină în poziţia 64 a domeniului II al proteinei respective, spre deosebire de reziduul tirozinic care ocupă acest loc în cazul celorlalte genotipuri, induce o afinitate mai mare pentru lipide (23).

Se presupune că steatoza hepatică care se corelează cu nivelul rezistenţei la insulină ar putea fi în general determinată nu numai de efectul steatogen viral, ci şi de acţiunea altor factori de risc, precum obezitatea cu dispoziţie predominant abdominală, diabetul zaharat, dislipidemiile sau, eventual, consumul de alcool (24). La aceşti pacienţi este de obicei vorba despre infecţia cu genotipurile 1, 2 sau 4, steatoza pare să se asocieze cu leziuni mai avansate de fibroză şi cu o progresie accelerată a acesteia, iar încărcarea grasă nu retrocedează după încheierea tratamentului antiviral (25). Este posibil ca prezenţa încărcării lipidice intracelulare să sensibilizeze ţesutul hepatic la inflamaţie şi/sau moarte hepatocitară programată prin apoptoză, care favorizează activarea celulelor stelate şi extensia fibrozei.

Unii cercetători susţin chiar că, în cazul genotipurilor virale non-3, gradul steatozei

alterează şansa obţinerii unui răspuns viral susţinut (26), sugerând că pacienţii cu hepatită cronică C şi steatoză importantă ar trebui să înceapă cât mai precoce tratamentul antiviral, chiar dacă activitatea inflamatorie depistată histologic este doar uşoară (24). Câteva date experimentale sugerează că, în situaţii precum infecţia cu genotip 1b, insulinorezistenţa precede dezvoltarea steatozei hepatice, părând a fi cauza şi nu consecinţa acesteia.

Există trei mecanisme care explică apariţia steatozei hepatice legate de infecţia cu virus C:

a. *scăderea exportului de lipide din hepatocite*, prin formarea şi secreţia în cantităţi reduse de particule VLDL:

Proteina *core* a virusului C inhibă activitatea MTP (*Microsomal Triglyceride Transfer Protein*), o enzimă implicată în calea de asamblare a particulelor VLDL prin catalizarea transferului lipidic spre reticulul endoplasmatic, unde se produce asocierea acestora cu apoproteinele B în cadrul unor complexe stabile. Unii cercetători au identificat chiar o corelaţie inversă între gradul steatozei hepatice din infecţia cu virus C şi nivelul ARNm al MTP, independent de genotipul implicat (27). Reducerea activităţii MTP, cu consecinţele menţionate anterior asupra exportului hepatocitar de VLDL, explică de ce la pacienţii cu hepatită cronică C se constată niveluri reduse ale trigliceridelor serice (28), iar la cei care asociază şi steatoză severă sunt prezente şi niveluri plasmatice reduse de colesterol şi apoB. După alţi cercetători, proteinele non-structurale virale pot şi ele să reducă activitatea MTP, chiar în absenţa proteinei *core* (29).

Acţiunea inhibitorie a proteinei *core* asupra MTP, deşi prezentă la toate genotipurile, este mai puternică în cazul genotipului 3 (30). În cazul genotipurilor 1 şi 2, mecanismul de inhibare a MTP pare a fi o reducere a transcripţiei sub influenţa rezistenţei la insulină şi a hiperinsulinismului reactiv; acesta din urmă inhibă expresia enzimei pe o cale care implică o kinază denumită MAP-Kerk (*Mitogen-Activated Extracellular Signal-Regulated Protein Kinase*).

Conform altor date provenite din studii experimentale, reducerea sintezei şi secreţiei de particule VLDL se poate explica şi prin intervenţia fenomenelor de stress oxidativ. Acumularea proteinei *core* în interiorul mitocondriei duce la alterarea transportului de electroni din cadrul lanţului respirator mitocondrial, având drept efect producţia crescută de ROS (*Reactive Oxygen Species*). În plus, activarea răspunsului imun de către virusul C induce şi ea stress oxidativ prin eliberarea unor citokine şi activarea macrofagelor. Acumularea ROS provoacă peroxidarea lipidelor şi proteinelor structurale, alterând şi aparatul celular secretor de VLDL (31); în plus, ROS au un efect de stimulare a formării de citokine, inclusiv TNF-α, ceea ce duce la agravarea insulinorezistenţei şi prin aceasta a steatozei (19).

b. *reducerea consumului mitocondrial de acizi graşi*, prin inhibarea proceselor de oxidare lipidică:

Este posibil ca proteina *core* a virusului C să determine modificări structurale ale membranei mitocondriale, cu consecinţe negative asupra β-oxidării lipidelor, ceea ce poate explica acumularea citoplasmatică a lipidelor şi apariţia steatozei.

Tot proteina *core* pare a fi responsabilă de inhibarea expresiei PPAR-α, un receptor nuclear implicat în reglarea transcripţiei mai multor gene ale metabolismului lipidic; acţiunea inhibitorie a proteinei *core* este

mai intensă în cazul genotipului 3. Reducerea activităţii PPAR-α conduce la (32):

- scăderea expresiei acilcoenzimaA-oxidazei şi a CPT1A (*Carnitine Palmitoyl Acyl-CoA Transferase 1*) mitocondriale; ambele sunt enzime cheie în lanţul β-oxidării mitocondriale, aşa încât scăderea activităţii lor enzimatice se traduce prin reducerea oxidării acizilor graşi;
- inhibarea expresiei Mdr2, o proteină transportoare situată în membranele canaliculare care controlează secreţia fosfolipidică biliară, conducând implicit şi la excreţia redusă prin bilă a acizilor graşi.

c. *creşterea sintezei de novo a acizilor graşi*, prin activarea expresiei factorului de transcripţie SREBP-1c (*Sterol Regulatory Element Binding Protein Signaling Pathway-1c*) şi a receptorului nuclear RXR-α (*Retinoid X Receptor-α*); hiperactivarea acestor molecule determină supraexpresia unor enzime precum acid gras-sintetaza, acetilcoenzimaA-carboxilaza şi stearoil-coenzimaA-desaturaza, cu roluri cheie în lipogeneza *de novo*. Probabil tot proteina *core* este cea care cauzează şi activarea SREBP, întrucât transfecţia *in vitro* cu aceasta a unor linii celulare a dus la creşterea ARN_m al SREBP şi la sinteza intrahepatocitară crescută de acizi graşi (33). Există însă şi date care atestă activarea SREBP de către proteina non-structurală 2 (34).

Se pare că steatoza hepatică existentă la pacienţii cu hepatită cronică C poate favoriza, la rândul ei, replicarea virală. Virusul C se asociază cu lipoproteinele LDL în cadrul unor particule lipo-virale care vor fi captate din torentul sanguin de către receptorii hepatocitari pentru LDL, intrând pe această cale în celulă. Pe de altă parte, unii cercetători au descoperit existenţa unor anomalii în metabolismul VLDL şi LDL, cu un catabolism redus al VLDL (ceea ce accentuează transformarea particulelor VLDL în LDL în curentul circulator) şi un catabolism crescut al LDL, care duce la încărcarea hepatocitelor cu lipidele captate din sânge; deşi nu are încă o explicaţie la nivel molecular, această constatare îşi poate găsi motivaţia în eventuale conexiuni fizice stabilite între virusul C şi particulele lipoproteice respective şi/sau în modificarea de către acesta a compoziţiei lor moleculare (35). În felul acesta, alterarea raportului plasmatic între particulele VLDL şi LDL poate favoriza legarea virusului de hepatocite, astfel încât – odată cu reducerea secreţiei hepatocitare de VLDL – se închide un cerc vicios prin care virusul C îşi promovează propria intrare şi diseminare intracelulară (24).

CONSECINŢE TERAPEUTICE ALE ASOCIERII INSULINOREZISTENŢĂ – STEATOZĂ – HEPATITĂ CRONICĂ CU VIRUS C

După cum am menţionat anterior, rezistenţa la insulină şi steatoza hepatică pot avea de multe ori consecinţe negative asupra evoluţiei bolii şi a responsivităţii la terapia antivirală standard. Ghidurile actuale nu conţin însă recomandări specifice pentru diagnosticul sau tratamentul particularizat al insulinorezistenţei la pacienţii cu hepatită cronică C. Există şi autori care propun ca aceştia să fie monitorizaţi periodic prin determinarea indicilor de insulinorezistenţă (spre exemplu, HOMA-IR) şi depistarea din timp a unor elemente clinice ale sindromului metabolic (care are drept element fiziopatologic central rezistenţa la acţiunea insulinei), precum excesul ponderal, dislipidemia sau hipertensiunea arterială (1,11).

În cazul patologiilor metabolice, tratamentul uzual al insulinorezistenţei constă

în măsuri de optimizare a stilului de viaţă (implementarea activităţii fizice şi eventuale modificări dietetice, ce urmăresc reducerea excesului ponderal) şi eventual în medicaţie insulinosensibilizantă în unele cazuri (diabet zaharat tip 2, ovar polichistic etc.). Dintre aceste metode terapeutice, utilitatea mijloacelor nonfarmacologice de scădere ponderală şi a tratamentului cu thiazolidindione începe să fie testată şi la pacienţii cu infecţie cronică cu virus C.

Există dovezi că scăderea în greutate la pacienţii obezi are un efect benefic de reducere a leziunilor de steatoză şi fibroză din hepatita cronică C şi de favorizare a unui rezultat pozitiv al tratamentului antiviral. Dealtfel, consecinţele negative ale obezităţii asupra eficienţei terapiei standard din hepatita C se explică prin:

- legătura cauză-efect existentă între obezitate şi insulinorezistenţă;
- statusul proinflamator caracteristic obezităţii, cu niveluri crescute ale TNF-α şi ale leptinei şi niveluri scăzute de adiponectină.

TNF-α este o citokină proinflamatorie şi care induce rezistenţă la insulină, existând dovezi că nivelul său se corelează invers proporţional cu răspunsul la terapia antivirală. *Leptina* este o adipocitokină secretată proporţional cu capitalul de masă grasă al organismului; în cazul multor pacienţi se înregistrează de obicei un grad de rezistenţă la acţiunile sale de promovare a catabolismului care a condus – prin paralelism cu insulina – la denumirea de leptinorezistenţă. Întrucât leptina favorizează răspunsul imun celular mediat de limfocitele Th1, care par a avea un rol central în răspunsul susţinut la interferon, s-a formulat ipoteza că leptinorezistenţa ar putea avea efecte negative asupra eficienţei terapeutice. *Adiponectina* este o adipocitokină cu acţiune antiinflamatorie şi de antagonizare a TNF-α, care se pare că are niveluri scăzute atât la pacienţii obezi, cât şi la cei cu hepatită cronică cu virus C (36).

O absorbţie redusă a peginterferonului după administrarea subcutanată la pacienţii obezi, explicată prin drenajul limfatic defectuos prezent la aceştia şi care conduce la o biodisponibilitate scăzută a medicaţiei (37).

Referitor la tratamentul cu thiazolidindione, studiile de durată scurtă sau medie în care pioglitazona a fost folosită ca premedicaţie şi/sau *add-on* la tratamentul antiviral standard oferă informaţii contradictorii, oscilând între lipsa oricărui beneficiu terapeutic asupra infecţiei cu virus C (chiar dacă s-a reuşit ameliorarea sensibilităţii la insulină) şi obţinerea unui răspuns virusologic pe termen scurt sau lung (38-42). Sunt necesare cercetări desfăşurate pe loturi extinse de pacienţi şi pe intervale mai mari de timp pentru a putea concluziona dacă adăugarea terapiei cu thiazolidindione la tratamentul antiviral standard reprezintă o direcţie terapeutică de valoare pentru viitor.

Alte echipe de cercetare au obţinut rezultate favorabile *in vitro* utilizând lovastatin sau acizi graşi polinesaturaţi. Efectul favorabil al statinelor se explică prin acţiunea lor asupra 3-hidroxi-3-metilglutaril-Co-Areductazei, care determină inhibarea căii mevalonatului şi reducerea proceselor de prenilare a proteinelor. Se formează astfel mai puţine proteine asociate – necesare includerii în construcţia membranelor celulare, inclusiv în cea a picăturilor lipidice (43). Referitor la efectul acizilor graşi, se pare că cei saturaţi şi cei mononesaturaţi sunt necesari replicării virale, pe când acizii graşi polinesaturaţi o inhibă (44).

Trecerea în revistă a datelor obţinute de cercetările ultimilor ani ne permite să observăm că infecţia cronică cu virus hepati-

tic C se transformă într-o boală cu tot mai multe particularități metabolice. Deşi cunoştințele respective sunt încă incomplete şi de multe ori contradictorii, ele oferă motive de încurajare celor care caută un tratament cât mai eficient al acestei boli virale hepatice, întrucât se speră că – prin controlul mecanismelor fiziopatologice metabolice – va fi posibilă creşterea randamentului terapeutic.

NOUTĂȚI

NOI DIRECȚII TERAPEUTICE ÎN NEFROPATIA INDUSĂ DE CYCLOSPORINA A

Activarea sistemului renină angiotensină aldosteron (SRAA) joacă un rol important în nefropatia indusă de cyclosporina A. Scopul acestui studiu este de a demonstra că administrarea de extract de ceai verde poate preveni apariția acestui tip de nefropatie. Pentru acest studiu au fost folositi şobolani care au fost împărțiți în patru grupuri (6 în fiecare grup) şi tratați 21 de zile: un grup de control(grupul 1) cărora li s:a administrat ser fiziologic, grupului 2 doar cyclosporină intaperitoneal 30 mg/kg/zi, grupului 3 cyclosporină şi extract de ceia verde 100 mg/kg/zi subcutanat iar grupului 4 doar extract de ceai verde. S-au observat nivele plasmatice crescute de uree şi creatinină în grupul 2 comparativ cu grupul 3 şi cu grupul 1. Analizele biochimine au arătat că activitatea plasmatică a reninei şi concentrația serică a aldosteronului au fost semnificativ crescute în grupul 2 față de grupul 1 şi semnificativ scăzute în grupul 3 față de grupul 2. Astfel, s-a demonstat că administrarea cyclosporinei creşte nivelele intrarenale ale reninei şi induce nefrotoxicitate. Efectele protective ale extractului de ceai verde în ceea ce priveşte nefropatia indusă de cyclosporină pot consta în blocarea SRAA. (Hyun HR, Hyun LK, Chung JH et al. Renoprotective effects of green tea extract on renin-angiotensin-aldosterone system in chronic cyclosporine-treated rats. *NephrolDial Transplant*. 2011; 26: 188-1193).

THROMBOTHIC COMPLICATION PATHOGENESIS IN CHRONIC MYELOPROLIFERATIVE DISORDERS AND MYELODISPLASTIC SYNDROMES (Abstract): Chronic myeloproliferative disorders (CMD) and Myelodisplastic Syndromes (MDS) represents a group of clonal pluripotent stem-cell pathologies. During their natural history, the clinical picture reveals both thrombosis and hemorrhage. The thrombosis could affect the microvessels, and also the large vessels, including even less usual territories (suprahepatic veins, porta vein, pulmonary vein). There are many factors contributing to thrombosis in myeloproliferative chronic disorders – the associated comorbidities, the numeric alterations of blood elements and also the disorders of the platelet's function. Thus, there were described quantitative and qualitative anomalies of platelet's receptors : GP Ib, GP IIb/IIIa, GP IV, GP VI, thrombopoietin receptor of the platelet cMPL, the increase of platelet activation; the increase of P selectin and thrombospondin and the increase on GP IIb/IIIa expression – they were all correlated with thrombosis. An important role has been attributed to JAK2 mutation, which affects the platelet receptor for thrombopoietin cMPL. Regarding the hemorrhage in chronic myeloproliferative syndrome, it is favored by many disorders in platelet's function, such as : the decrease of von Willebrand factor's receptor of the platelet, which leads to acquired Bernard Soulier syndrome; quantitative and qualitative disorders of dense granules of the platelet, decrease of the secretion and platelet aggregation after epinephrine, ADP and collagen stimulation. It was also described the acquired von Willebrand syndrome, most frequently type 2. **Key words**: MYELOPROLIFERATIVE CHRONIC SYNDROME, THROMBOSIS, HEMORRHAGE, PLATELET DYSFUNCTION

Sindroamele mieloproliferative cronice cuprind boli hematologice clonale care apar prin afectarea celulei hematopoietice pluripotente. Dintre acestea leucemia mieloidă cronică caracterizată prin prezenţa fuziunii BCR-ABL şi 3 boli mieloproliferative cronice Ph - policitemia vera, trombocitemia esenţială şi metaplazia mieloidă cu mielosclerozã. Conform noii clasificări OMS din acest grup mai fac parte mastocitoza sistemică, leucemia cronică cu eozinofile, leucemia cronică cu neutrofile, leucemia mielomonocitară cronică.

În evoluţie, tabloul clinic al acestor boli poate include şi manifestări trombotice sau hemoragipare. Manifestările trombotice sunt evidente mai ales la nivelul microcirculaţiei dar şi la nivelul vaselor mari – vene, artere (11). Acestea pot apare în evoluţie sau la debutul bolii, în faza preclinică, fiind necesare investigaţii pentru trombofilia dobândită, mai ales în cazul pacienţilor cu trom-

boze venoase situate pe vase mai rar afectate (vene suprahepatică, porta, pulmonară, sindromul Budd Chiari) (11).

La 32% dintre pacienţii cu SMPC s-au observat manifestări trombotice (arteriale, microvasculare) (21).

Manifestările hemoragipare sunt mai rare şi pot fi exprimate prin hemoragii mucoase şi cutanate minore care uneori pot preceda hemoragiile digestive superioare (11,12). Boala von Willebrand dobandită (cel mai adesea prin deficitul multimerilor de dimensiuni mari), o reducere a activităţii procoagulante a trombocitelor sau forme dobândite de sindrom Bernard Soulier au fost de asemenea raportate la pacienţii cu mieloproliferări cronice (16).

PATOGENEZA TROMBOZELOR

Cunoştiinţele despre patogeneza trombozelor în sindroamele mieloproliferative cronice sunt inferioare comparativ cu progresul cunoştinţelor din domeniul trombozelor. Cauzele care limitează cercetarea în acest domeniu sunt perioada lungă de urmărire a evoluţiei clinice, unii factori clinici asociaţi (impactul comorbidităţilor, terapia citoreductivă). Factori multipli contribuie la patogeneza trombozei – incluzând creşterea masei celulare în policitemia vera, creşterea posibilă a trombocitelor, activarea trombocitară şi leucocitară şi interacţiunea lor cu formarea de agregate leucotrombocitare în asociere cu factori protrombotici şi factori endoteliali (11).

În sindroamele mieloproliferative cronice apar numeroase **anomalii ale receptorilor trombocitari atât de natură cantitativă cât şi calitativă**. Aceştia sunt GPIb, GP IIb/IIIa, GPIV, GPVI şi receptorul pentru trombopoietină cMPL. Variabilitatea receptorilor trombocitari este de asemenea determinată genetic şi câteva studii au demonstrat că polimorfismul glicoproteinelor trombocitare poate contribui la tromboze (15,16). Prezenţa alelei PLA_2 a GPIIIa a fost asociată cu o creştere a incidenţei trombozelor arteriale dar această concluzie a studiului efectuat necesită confirmare în studii mai ample. Relevanţa polimorfismului GP1a, GP1bα şi integrinei α2β1 în special la pacienţii cu mieloproliferări cronice rămâne neclară (15,16). Într-un studiu s-a arătat că reducerea expresiei c-MPL este specifică la pacienţii cu policitemia vera şi nu este evidenţiată la pacienţii cu poliglobulie secundară (13).

Activarea trombocitară în mieloproliferările cronice a fost descrisă cu mult timp în urmă. Mai recent, creşterea expresiei P selectinei, trombospondinei şi a receptorului GPIIb/IIIa a fost corelată cu tromboza (16). Studiile efectuate au arătat că la pacienţii cu sindroame mieloproliferative cronice au fost evidenţiate o scădere a expresiei şi a capacităţii funcţionale a receptorului GPIIb/IIIa (CD41/CD61), receptorului pentru fibrinogen, fibronectina, vitronectina, trombospondina, factor Willebrand. De asemenea s-a asociat şi cu o scădere a fixării FvW pe trombocit (16).

Un studiu efectuat în 1989 în Japonia a urmărit **invesigarea anomaliilor influxului de calciu în trombocite la pacienţii cu boli mieloproliferative cronice**. Influxul calciului în trombocite a fost mai scăzut la pacienţii cu mieloproliferări cronice comparativ cu lotul de control. Concluzia autorilor a fost că anomaliile GP IIb/IIIa sunt implicate în scăderea influxului de calciu în trombocitele pacienţilor cu mieloproliferări cronice (17).

Patogeneza activării trombocitare în mieloproliferările cronice nu este cunoscută, deşi un număr mare de pacienţi au un deficit de lipooxigenază care poate creşte capacitatea endoperoxidazelor în producerea tromboxanului A2.

O explicatie alternativă a creşterii activării trombocitare include un efect al mutaţiei JAK2 (2). Datele recente sugerează că mutaţia JAK2 afectează receptorul cMPL--receptorul pentru trombopoietină de pe trombocit (fig. 1).

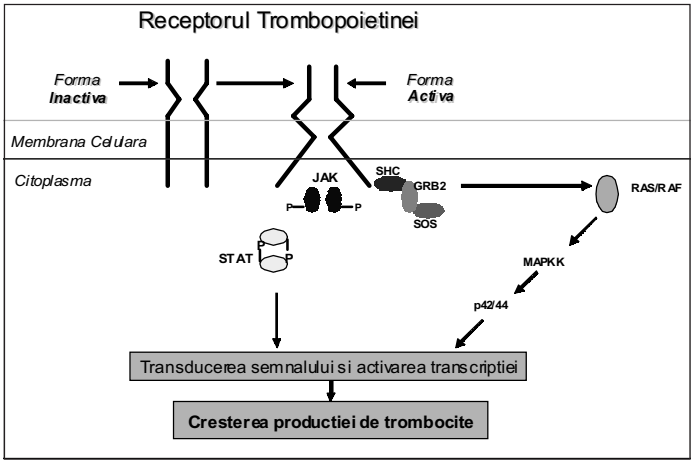

Fig. 1. Relaţia între mutaţia JAK2 şi receptorul cMPL-receptorul pentru trombopoietină

În mieloproliferările cronice mutaţia apare la nivelul celulei progenitoare multipotente (6). Progenitorii homozigoţi sunt mai frecvenţi la pacienţii cu policitemia vera şi s-a întâlnit rar la cei cu trombocitemie esenţială (9). Mutaţiile JAK2V617F apar la 90–95% din pacienţii cu PV, 50–70% din pacienţii cu TE, şi 40–50% din pacienţii cu MMM (14,15).

Această mutaţie poate apare în procente reduse şi în alte mieloproliferări acute sau cronice Ph(–) precum şi în mielodisplazii (1,3,7,14,15). Prezenţa mutaţiei JAK2 a fost evidenţiată la pacienţii cu leucemie acută mieloblastică, mai ales vârstnici, existând posibilitatea ca aceştia să prezinte sindroame mieloproliferative cronice anterior rămase nediagnosticate. Date recente au arătat că mutaţia JAK2 este prezentă într-o proporţie semnificativă la pacienţii cu leucemie acută mieloblastică care urmează evoluţiei sindroamelor mieloproliferative cronice. La pacienţii cu leucemie acută mieloblastică de novo incidenţa acestei mutaţii este redusă (10,12).

Domeniul intracitoplasmatic al acestui receptor este asociat cu JAK2, membru al familiei kinazelor Janus. Trombopoetina stimulează fosforilarea unor numeroase proteine printre care kinazele Janus JAK2 si TYK2 (17). Trombopoetina şi receptorul ei sunt cheile de control pentru reglarea numărului trombocitelor majoritatea pacienţilor cu policitemia vera şi metaplazie mieloidă cu mielofibroză au o reducere a nivelului receptorilor pentru trombopoietină şi o incompletă glicozilare a acestora. Acest defect nu a fost găsit la alte glicoproteine membranare trombocitare (GP IIb, multimerin). Defectul se corelează însă cu durata bolii şi hematopoieza extramedulară (8,16).

În sindroamele mieloproliferative cronice apar şi alte modificări ale receptorilor membranari trombocitari care pot favoriza manifestările trombotice-**GP IV (CD 36) receptor pentru trombospondina** eliberată din plachete în cursul secreţiei. Contribuie la consolidarea agregatelor trombocitare şi agregare ireversibilă. În bolile mieloproliferative cronice a fost observată o creştere a expresiei (25,26)**.** Prezenta formă proteolizată de 160Kda a trombospondinei (TSP) a fost evidenţiată la toţi pacienţii cu trombocitemie esenţială şi nu a fost găsită la pacienţii cu trombocitoză secundară (1). Într-un studiu s-a arătat că nivelul plasmatic al GP IV şi al celor de suprafaţă asociate cu TSP tind să se normalizeze în timpul tratamentului cu interferon pe când prezenţa formelor alterate ale trombospondinei persistă (18).

Trombocitele activate interacţionează cu alte componente ale sângelui şi au capacitatea de a provoca activare sau distrucţie a endoteliului.

Unele studii au demonstrat creşteri şi ale VEGF care demonstrează şi o **creştere a activării endoteliului**. Activarea leucocitelor (neutrofile şi monocite determină declanşarea coagulării prin eliberarea granulelor conţinute, formarea de agregate cu trombocitele, eliberarea unor citokine inflamatorii, a superoxidului de oxigen care produc afectarea endoteliului vascular (5). Interacţiunea între neutrofile şi trombocite apare după cascada adeziunii în care CD62P se leagă de P selectina de pe neutrofil. Fixarea adeziunii se face prin legarea CD11b a $ß_2$-integrinei în complex cu CD18 cu GP Ib trombocitar sau a fibrinogenului la GP IIb/IIIa trombocitară. În unele studii s-au arătat creşteri ale expresiei CD 62P, CD11b, CD 42b şi a complexelor CD11b/CD42b precum şi a complexelor CD62P/ CD11b la pacienţii cu policitemia vera şi trombocitemia esenţială (5). Studii recente au arătat o asociere între mutaţia JAK2 şi creşterea activării leucotrombocitare cu formare de agregate trombocitare (2).

Administrarea aspirinei poate fi eficientă prin impiedicarea formării acestor agregate. Hydroxiureea poate şi ea contribui la reducerea acestor agregate, posibil precum şi prin supraexpresia genei endotelinei 1 şi ICAM-1 ca şi creşterea nivelului oxidului nitric (1,4,5).

PATOGENEZA SINDROAMELOR HEMORAGIPARE

Receptorul trombocitar cel mai afectat care poate explica prezenta sindroamelor hemoragipare este GP Ib/IX (CD 42) receptor pentru factorul Willebrand. Capătul terminal este scindat de proteaze incluzând calpaina trombocitară rezultând un fragment solubil, glicocalicin, circulant în plasma cu valori serice normale 1-3μg/ml. Este proporţional cu producţia trombocitară. Acest receptor poate scădea cantitativ în sindroamele mieloproliferative cronice ducând la o variantă dobandită de sindrom Bernard Soulier (16).

La pacienţii cu leucemie acută, sindroame mielodisplazice şi mieloproliferative cronice au fost în literatură anomalii cantitative şi calitative ale granulelor dense trombocitare ale corpusculilor intracelulari (conţinând ATP, ADP, calciu, calcitonină şi pirofosfat) (28). Studii relativ recente au arătat o asociere între modificările granulelor dense trombocitare şi descoperirea leucemiei acute mieloblastice (27). Defectul apare ca şi consecinţă a anomaliilor de formare a acestor granule mai curând decât prezenţa unor vezicule goale sau o scădere a conţinutului acestora, consecinţă a activării trombocitare asociată secreţiei. Rezultatele sugerează că defectul granulelor dense trombocitare asociat cu leucemia acută sau sindromul mielodisplazic poate fi rezultatul alterării cromozomiale în linia celulară megacariocitară conducând la scăderea formării granulelor dense (27,28).

În bolile mieloproliferative cronice şi în mielodisplazii scade secreţia şi agregarea trombocitară după stimularea cu epinefrină, ADP, colagen. Defectul agregării la stimularea cu epinefrină se traduce prin absenţa primei unde de agregare. (28). Se mai poate observa în mieloproliferările cronice o scădere a multimerilor de dimensiuni mari (19). Un grup de cercetători din Argentina au luat în studiu un grup de 99 pacienţi cu boala von Willebrand dobândită (21). Aceştia au constatat că 75% dintre pacienţi asociau sindrom mieloproliferativ cronic în special policitemia vera sau trombocitemie esenţială (21).

Cel mai frecvent tip de boală Willebrand întâlnit a fost tip 2 (67,7%) Anomaliile timpului de sângerare, nivelul de factor VIII au fost observate la 83,3% din cazuri. Sângerările au fost prezente la 38,4% dintre pacienţi mai frecvent la pacienţii fără asociere de SMPC 58,3% vs pacienţi cu SMPC (32%) (p 0,022) cu o preponderenţă mai mare la femei (21).

Conform rezultatatelor publicate de Sanchez-Luceros et al. se conturează ideea că sin-

dromul von Willebrand dobândit la pacienţii cu SMPC este doar un diagnostic de laborator fără a fi evident clinic în multe cazuri deşi sângerările şi manifestările ischemice pot fi prezente. În schimb, la pacienţii fără SMPC Boala Von Willebrand dobândită se manifestă clinic mai evident prin episoade hemoragipare severe (21).

CONCLUZIE

Cunoaşterea aprofundată a mecanismelor care stau la baza diatezei trombotice şi hemoragipare în bolile celulei stem permite o abordare interdisciplinară şi complexă a problematicii, punând în discuţie aplicarea terapiilor cu viză patogenică, cu accentul pe terapiile cu ţintă moleculară.

FEATURES OF ARTERIAL BLOOD PRESSURE IN METABOLIC SYNDROME (Abstract): The metabolic syndrome has high prevalence in hypertensive patients. Its presence leads to the early appearance of target organ damage, particularly of left ventricular hypertrophy. The 24-hour ambulatory monitoring of arterial blood pressure allows the estimation of the BP Load. The BP Load accomplishes the best correlation between the systolic blood pressure and left ventricular hypertrophy. The purpose of this study is to identify the prevalence of the metabolic syndrome and the particularities of hypertension in hypertensive patients suffering from metabolic syndrome, using 24 hour continuous blood pressure monitoring. **Material and method:** During a three years period (2007-2009), 303 hypertensive patients were assessed at the Internal medicine Section of the County Emergency Hospital in Bacau. **Results:** The metabolic syndrome occurred in 60.1% of hypertensive patients. The batch with metabolic syndrome contained 181 patients, a female/male ratio of 3,41 to 1, average age: 66.50 ± 10.28 years, 60.8% coming from urban environment. The monitorised systole-diastolic tension values studies indicate isolated systolic hypertension. No dipper and reverse dipper tensional profiles prevail. **Conclusions:** In patients with isolated systolic hypertension, the association of the metabolic syndrome is the main cardiovascular risk and is associated with increase of diastolic blood pressure, presence of left ventricular hypertrophy and increased hypertensive Load values. **Key words:** BLOOD PRESSURE, METABOLIC SYNDROME, BP LOAD

Sindromul metabolic recunoaşte inaltă prevalenţă în populaţia generală şi este întâlnit la circa o treime din pacienţii hipertensivi, mai ales la cei cu hipertensiune necontrolată.

Sub aspect morfofuncţional creşte stiffness-ul arterial cu reducerea distensibilităţii arteriale la pacienţii hipertensivi cu sindrom metabolic.

De asemenea, se raportează creşterea prevalenţei hipertrofiei ventriculare stângi, a disfuncţiei diastolice, aterosclerozei carotidiene precoce, reducerea distensibilităţii aortice, retinopatiei hipertensive şi microalbuminuriei (1). Apariţia precoce a leziunilor subclinice de organ poate constitui predictor independent de evenimente adverse vasculare şi poate explica parţial asocierea sindromului metabolic cu risc înalt cardiovascular şi renal.

Monitorizarea ambulatorie a presiunii arteriale se corelează mai bine cu leziunile de organ şi evenimentele cardiovasculare decât măsurarea manuală, constituind un instrument diagnostic şi prognostic deosebit de util la pacientul hipertensiv (2,3,4).

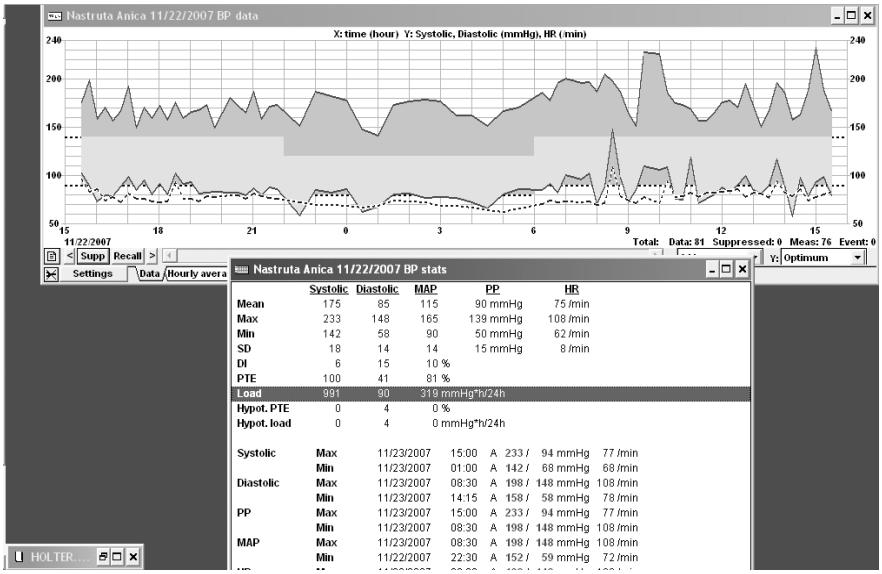

Fig. 1. Sarcina de presiune (LOAD)

Un parametru deosebit de util în practică, derivat din determinările tensiunii arteriale sistolice si diastolice, este denumit BP load (sarcina de presiune sau impactul hiperbaric), care reflectă procentul parametrilor presionali sistolici şi diastolici care depăşesc valorile normale. Practic este vorba de aria de sub curba tensională şi limita superioară a normalului. Unitatea de măsură este reprezentată de mmHg*h/24 ore, iar valoarea normală este de 60 mmHg*h/24 ore. Acesta poate diferenţia formele susţinute de formele episodice de hipertensiune arterială (5). Diversele studii au stabilit corelaţia acestui indicator cu leziune de organe ţintă, corectarea lui devenind obiectiv terapeutic (fig. 1).

Hipertensivul vârstnic se caracterizeaza prin labilitatea valorilor tensionale diurne, instalând peakuri hipertensive simptomatice chiar sub tratament corect condus, ceea ce defineşte HTA intermitentă. Deoarece mare parte dintre aceşti pacienţi prezintă afectare de organe ţintă, Verdecchia sugerează că încărcarea hipertensivă (sarcina de presiune, LOAD) poate fi mult mai strâns corelată cu riscul cardiovascular, când comparăm cu nivelurile medii ale TA înregistrate prin monitorizare continuă ambulatorie (6).

Estimarea sarcinii hipertensive (BP load) oferă relaţii mai precise despre expunerea sistemului cardiovascular la presiune pe parcursul a 24 ore (7). Numeroase evidenţe sugerează o relaţie directă şi semnificativă între sarcina hipertensivă şi leziuni de organe ţintă, acest parametru calculat numai prin monitorizare continuă are valoare predictivă superioară în relaţie cu morbiditatea şi mortalitatea cardiovasculară faţă de măsurarea izolată clinic a tensiunii arteriale. Mărimea sarcinii hipertensive realizează cea mai bună corelare cu HVS, în unele studii s-a demonstrat până la 90% corelarea HVS cu LOAD sistolic care depăşeşte 50% (8).

Scopul studiului este să identifice prevalenţa sindromului metabolic în rândul populaţiei hipertensive şi particularităţile hipertensiunii arteriale la pacienţii hipertensivi cu sindrom metabolic, utilizând monitorizarea continuă pe 24 ore a tensiunii arteriale.

MATERIAL ŞI METODĂ

Raportat la populaţia judeţului Bacău (n=725.005 locuitori), cu o eroare de eşan-

tionare de ±5,6% faţă de IC95% s-a stabilit dimensiunea eşantionului reprezentativ şi anume 303 pacienţi.

Medicină Internă a Spitalului Judeţean de Urgenţă Bacău. Selecţia pacienţilor a fost efectuată utilizând ca metodă selecţia sistemică, în sensul că în perioada de screening a fost examinat pentru studiu al cincilea pacient hipertensiv prezentat la consultaţie sau la internare şi care a prezentat hipertensiune arterială la prima vizită medicală. Diagnosticul de HTA s-a efectuat prin măsurarea TA la nivelul braţului bilateral, respectând recomandările Ghidului de hipertensiune din 2003 şi 2007. Pentru diagnostic şi stadializare s-a luat în considerare valoarea cea mai mare. La această primă vizită s-a solicitat semnarea consimţământului informat al pacientului în vederea introducerii în studiu. Pacienţii care au semnat formularul de consimţământ au fost invitaţi la alte două vizite medicale la intervale de o săptămână. Pacienţii care au prezentat valori definitorii pentru diagnosticul clinic de HTA la vizita din săptămâna a treia au fost randomizaţi şi incluşi în studiu în vederea monitorizării continue a tensiunii arteriale.

Au fost screenaţi un număr de 391 pacienţi la prima vizită medicală. Dintre aceştia 32 au prezentat tensiunea arterială normală la următoarele 2 vizite, 27 de pacienţi nu au mai revenit la una sau la ambele vizite din motive de necomplianţă, ceilalţi 332 pacienţi au intrat în studiu. După analizarea traseelor înregistrate prin monitorizarea continuă pe 24 ore a tensiunii arteriale, 11 pacienţi au avut trasee neinterpretabile (artefacte multiple, număr mic de măsurători corecte, decuplări ale manşetei) şi au fost excluşi. Alţi 18 pacienţi au înregistrat valori medii sistolodiastolice normale şi sarcina de presiune (load) absentă. Deoarece aceştia din urmă nu aveau antecedente hipertensive şi nu urmau tratament antihipertensiv, au fost consideraţi cu hipertensiune de halat alb şi au constituit un sublot analizat separat. Astfel au rămas în studiu 303 pacienţi hipertensivi, care au fost supuşi analizei statistice.

Monitorizarea continuă a tensiunii arteriale s-a efectuat cu sistemul de monitorizare care se numeşte ABPM-04, care corespunde cerinţelor protocoalelor de validare ale BHS (British Hypertension Society) şi al AAMI referitoare la tensiometrele automate.

REZULTATE

În studiul nostru, din 303 pacienţi hipertensivi, 181 de pacienţi (60,1%), cu raportul F/M = 3,41/1, au îndeplinit criterii de sindrom metabolic. Criteriile de diagnostic pentru sindromul metabolic au fost cele oferite de NCEP-ATPIII (minim 3 criterii), criteriul de bază fiind tensiunea arterială mai mare sau egal cu 135/85 mmHg. Vârsta medie a pacienţilor a fost de 66,50 ± 10,28 ani, variind între 18 şi 83 ani. De notat ponderea crescută a pacienţilor din mediul urban (60,8%).

Valorile tensiunii arteriale medii monitorizate pe 24 ore, în funcţie de sex, vârstă şi mediu de proveniență relevă valori ale tensiunii arteriale sistolice de 134,5 mmHg la pacienţii cu vârsta sub 65 ani şi 140,13 mmHg la grupa de vârstă peste 65 ani. Remarcăm creşterea valorilor presionale pe măsura înaintării în vârstă, evidenţiindu-se diferenţe semnificativ mai mari ale tensiunii sistolice la grupa de vârstă de peste 65 ani

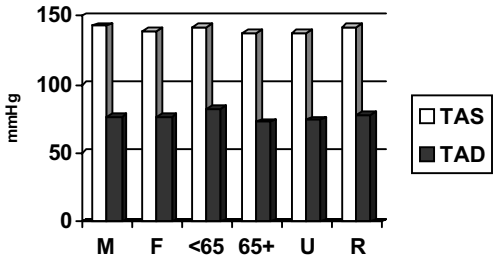

Fig. 2. Valori medii ale tensiunii arteriale monitorizate 24 ore pe sex, grupe de vârstă şi mediu de proveniență

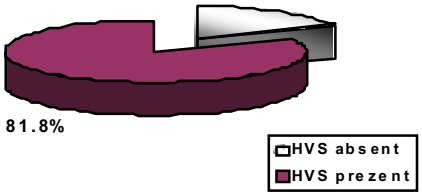

Fig. 3. Prezenţa HVS la lotul cu sindrom metabolic

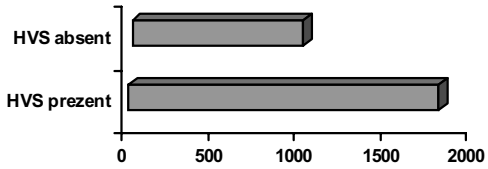

Fig. 4. Sarcina hipertensivă în funcţie de prezenţa HVS

($p < 0,05$). Valorile medii diastolice sunt 72 mmHg, respectiv 75 mmHg şi nu prezintă diferenţe semnificative între grupele de vârstă. În ansamblu tensiunea sistolică medie prezintă valori ce depăşesc valoarea de referinţă de 135 mmHg iar valori ale tensiunii arteriale diastolice nu ajung până la valoarea de referinţă de 85 mmHg, ceea ce sugerează că predomină hipertensiunea sistolică izolată la majoritatea pacienţilor (fig. 2).

Sub aspectul profilului circadian, dintre cei 181 de pacienţi hipertensivi cu sindrom metabolic un număr de 54 pacienţi (29,8%) au prezentat profil tensional non dipper, profil dipper fiziologic a fost înregistrat la 50 pacienţi (27,6%), reversedipperi au fost 49 cazuri (27,1%) şi 3 cazuri hiper dipper (1,7%).

Prelucrarea statistică a valorilor tensionale monitorizate, în funcţie de caracteristicile epidemiologice, relevă următoarele aspecte :

- la sexul masculin, atât valorile medii cât şi cele minime ale tensiunii sistolice sunt semnificativ mai mari comparativ cu cele monitorizate la sexul feminin ($p < 0,05$) ;
- indexul diurn relevă că lotul de pacienţi cu sindrom metabolic este preponderent non dipper, cu diferenţe semnificative între sexe ($p < 0,01$) ;
- valorile medii ale tensiunii diastolice şi cele minime sunt semnificativ mai mari la sexul masculin ($p < 0,01$), cu variaţii semnificative ale indexului diurn ($p < 0,05$) ;
- vârsta de 65 de ani a fost aleasă ca valoare de referinţă pentru compararea tensiunii arteriale deoarece vârsta medie a lotului cu sindrom metabolic a fost evaluată la 66,50 ani, evidenţiindu-se diferenţe semnificativ mai mari ale tensiunii sistolice la grupa de vârstă de peste 65 ani ($p < 0,05$) ; tensiunea diastolică nu prezintă diferenţe semnificative între grupele de vârstă ;
- pe medii de provenienţă mediile sistolo-diastolice nu evidenţiază diferenţe semnificative.

La pacienţii cu sindrom metabolic, în funcţie de prezenţa HVS pe electrocardiogramă şi valorile sarcinii hipertensive (load) pentru TA sistolică s-au evidenţiat următoarele aspecte :

- prezenţa HVS a fost identificată la 148 dintre pacienţii lotului cu sindrom metabolic (81,8%)(fig.3) ;
- valorile load au avut o variabilitate în intervalul 0 – 1858 mmHg*h/24h (fig.4) ;
- s-au înregistrat semnificativ mai multe cazuri cu load sub 500 la pacienţii cu HVS prezent ($p = 0,035$)(fig.5) ;
- valorile medii ale load au fost semnificativ mai crescute la pacienţii cu HVS prezent ($p < 0,01$)(fig.6).

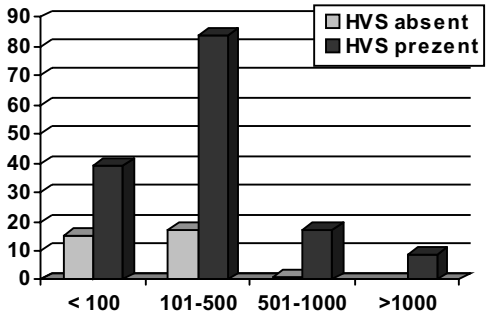

Fig. 5. Nivelul sarcinii hipertensive în funcţie de prezentţa HVS

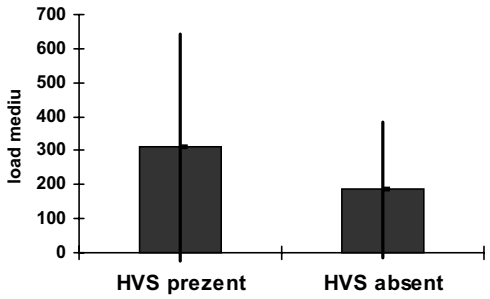

Fig. 6. Valorile medii ale sarcinii hipertensive în funcţie de HVS

DISCUŢII

Hipertensiunea arterială este adesea parte a unei constelaţii de anormalităţi clinice şi metabolice, realitate remarcată încă din 1920. Sindromul metabolic, în concepţia modernă poate fi trasat de la propoziţia lui Reaven din 1988, care a reunit sub denumirea de „sindrom X metabolic" asocierea hipertensiunii arteriale cu obezitatea abdominală (sau viscerală), dislipidemia aterogenă (HDL-colesterol scăzut, trigliceride crescute), intoleranţa la glucoză şi insulino-rezistenţa, acest ultim parametru fiind elementul central al sindromului (9).

Diagnosticul sindromului metabolic are importanţă deosebită la persoanele nediabetice deoarece identifică riscul crescut de dezvoltare a bolilor cardiovasculare, în concordanţă cu asocierea factorilor de risc implicaţi (10). În cazul identificării uneia dinre componente, este indicată căutarea sistematică a celorlalte elemente definitorii.

Definiţia originală şi cea revizuită a NCEP-ATPIII (National Cholesterol Education Program – Adult Treatment Pannel) este recomandată de Asociaţia Americană a Inimii pentru uzul clinic (11,12). Aceasta identifică 6 componente ale sindromului metabolic în relaţiile cu bolile cardiovasculare: obezitatea abdominală, dislipidemia aterogenă, creşterea presiunii sanguine, rezistenţa la insulină, intoleranţă la glucoză, statusul proinflamator şi protrombotic. Apariţia precoce a leziunilor subclinice de organ poate constitui predictor independent de evenimente adverse vasculare şi poate explica parţial asocierea sindromului metabolic cu risc înalt cardiovascular şi renal.

Date din studiul PROSPER (Prospective Study of Pravastatin in the Elderly at Risk) susţin că dintre componentele sindromului metabolic doar hipertensiunea arterială şi alterarea toleranţei la glucoză au valoare predictivă semnificativă pentru riscul cardiovascular (13). Un foarte recent studiu italian (14), studiul SardiNIA, demonstrează că elementele sindromului metabolic accelerează modificările morfologice şi funcţionale arteriale specifice vârstei.

Valorile tensiunii arteriale măsurate prin monitorizare 24 ore se corelează net superior cu riscul de leziuni a organelor ţintă. Primele evidenţe au fost legate de hipertrofia ventriculară stânga.

În studiul nostru 60,1% dintre pacienţii hipertensivi prezintă sindrom metabolic, cu pondere crescută a sexului feminin şi a populaţiei din mediul urban.

Vârsta medie a lotului fiind 66 ani, explică predominenţa hipertensiunii sistolice izolate la majoritatea pacienţilor.

Monitorizarea continuă pe 24 ore a tensiunii arteriale a evidenţiat creşterea progresivă a tensiunii sistolice odată cu înaintarea în vârstă dar şi creşterea nesemnificativă statistic a tensiunii diastolice, aspect datorat coexistenţei sindromului metabolic la vârstnici. Valorile tensiunii arteriale sunt semnificativ mai mari la sexul masculin, atât sistolice cât şi diastolice şi se însoţesc de alterarea profilului circadian.

Peste 80% dintre pacienţi au prezentat HVS electrocardiografică. Corelând HVS cu sarcina hipertensivă înregistrată prin monitorizare se remarcă predominenţa sarcinilor hipertensive uşoare şi medii (< 500 mmHg*h/24h) la majoritatea pacienţilor cu HVS însă valorile medii ale sarcinii presionale au fost semnificativ mai crescute la pacienţii cu HVS prezent.

CONCLUZII

Prevalenţa sindromului metabolic este foarte înaltă în rândul populaţiei hipertensive din aria geografică a judeţului Bacău şi creşte cu înaintarea în vârstă.

Predomină hipertensiunea sistolică izolată caracteristică populaţiei vârstnice, cu creşterea tensiunii arteriale sistolice odată cu înaintarea în vârstă dar şi creşterea tensiunii diastolice specifice sindromului metabolic.

Hipertensivii de sex masculin prezintă forme mai severe de hipertensiune, cu profil circadian patologic în proporţie semnificativ mai crescută.

Hipertrofia ventriculară stângă este întâlnită la 4 din 5 hipertensivi cu sindrom metabolic. Valorile medii ale sarcinii hipertensive sunt semnificativ mai crescute la hipertensivii cu HVS prezentă.

Monitorizarea continuă a tensiunii arteriale permite identificarea profilului tensional şi a sarcinii hipertensive. La hipertensivii cu sindrom metabolic predomină profilul nondipper şi reversedipper.

La pacienţii cu hipertensiune sistolică izolată, asocierea sindromului metabolic reprezintă principalul risc cardiovascular şi se asociază cu creşterea tensiunii diastolice, prezenţa hipertrofiei ventriculare stângi şi valori crescute ale sarcinii hipertensive.

HELYCOBACTER PYLORI- FRIEND OR FOE ? (Abstract) : *Helicobacter pylori* (*H. pylori*) is the bacterium that causes the most common infection in the world. Epidemiological studies show that over 50% of the population is infected, there are areas where virtually the entire population present the infection since childhood. Although the stomach seems to be a „hostile" environment for the development of microorganisms due to the acid pH not fit for life, it may be infected ; the first spiral organisms were described at this level as early as 1874. These microorganisms were isolated by Waren and Marshall in 1982 and named *Campylobacter pyloridis*. In 1989 Goodwin renamed the bacterium *Helicobacter pylori*. *Helicobacter pylori* is thus a bacterium which „manages" to survive in gastric acid environment producing an infection which, untreated, is likely to persist the entire life. This feature explains the high rate in the spread of the infection. The infection manifests itself in different ways, depending on the pathogenic strain and the host response, the majority of those infected being asimptomatic or paucysimptomatic. The great achievement of Warren and Marshall,who were rewarded with a Nobel prize in 2005, was to demonstrate that *H. pylori* can lead to gastric cancer, the bacteria being categorized as an oncogene agent. The anti *H. pylori* „campaign" was only a step away… and yet, the bacterium has been living in the stomach for centuries. We will try to list the pros and cons of *H. pylori* infection, when and how the infection should be treated, clearly indicating groups of patients in which eradication is absolutely mandatory. **Key words** : *HELICOBACTER PYLORI,* GASTRIC CANCER, GASTRITIS

Helicobacter pylori (*H. pylori*) este bacteria care determină cea mai răspândită infecţie de pe glob. Studiile epidemiologice arată că peste 50% din populaţie este infectată, existând zone în care practic toată populaţia prezintă infecţia încă din copilărie (1).

Deşi stomacul pare a fi un mediu „ostil" dezvoltării microorganismelor dat fiind pH-ul acid impropriu vieţii, acesta poate fi infectat, primele microorganisme spiralate fiind descrise la acest nivel încă din anii 1874 (2,3). Warren şi Marshall în 1982 izolează pentru prima dată o bacterie în stomac pe care o numesc *Campylobacter pyloridis* (4). În 1989 Goodwin redenumeşte această bacterie *Helicobacter pylori* (5).

Helicobacter pylori este o bacterie ce „reuşeşte" să supravieţuiască în mediu acid gastric producând o infecţie care, netratată, pare a persista toată viaţa. Această particularitate explică rata mare de răspândire a infecţiei. Mecanismul principal de transmitere a bacteriei este fecal-oral. Forma de manifestare a infecţiei este diferită, depinzând de tulpina patogenă şi de răspunsul gazdei. Majoritatea celor infectaţi sunt asimptomatici sau paucisimptomatici.

Marele merit a lui Warren şi Marshall, care au fost recompensaţi în 2005 cu premiul Nobel, a fost acela de a demonstra că *H. pylori* poate duce la apariţia cancerului

gastric, bacteria fiind trecută pe lista agenţilor oncogeni. De aici şi până la „campania" anti *H. pylori* nu a fost decât un pas... şi totuşi, bacteria convieţuieşte în stomac de secole.

Vom încerca să aducem argumente pro şi contra infecţiei cu *H. pylori*, cum şi când trebuie tratată infecţia, cu precizarea clară a grupelor de pacienţi la care eradicarea este absolut obligatorie.

EPIDEMIOLOGIE

H. pylori produce o infecţie cronică gastrică care survine după un episod acut, petrecut în copilărie în ţările cu un standard socio-economic scăzut şi la adult în cele dezvoltate. Prevalenţa infecţiei în ţările în curs de dezvoltare este la adult de 80-90% iar în ţările dezvoltate nu depăşeşte 60%. Incidenţa infecţiei este maximă în primii ani de viaţă, riscul dobândirii acesteia în timpul vieţii adulte scăzând exponenţial. Prevalenţa infecţiei creşte cu vârsta (6,7).

Gazda principală este reprezentată de specia umană. *H. pylori* are tropism tisular strict, reprezentat de celulele antrale gastrice. Poate fi identificat nu doar în stomac ci şi în zonele de metaplazie gastrică din duoden, esofag, fornix, diverticul Meckel, rect (8). Specii similare se pot întâlni şi la primate.

Teoretic toate persoanele sunt susceptibile la infecţie. Marea majoritate a studiilor indică un risc egal de infecţie cu *H. pylori* pentru ambele sexe. Incidenţa cea mai mare a infecţiei este în primii ani de viaţă şi în special în primul, fiind de 3,8% în ţările în curs de dezvolatare şi de 2,7% în ţările dezvoltate (9).

Factorii genetici (răspunsul imun al gazdei) sunt cei care, împreună cu factorii de virulenţă ai *H. pylori*, dictează tipul de infecţie cu *H. pylori* (gastrită, ulcer, cancer etc.) (10).

Consumul de alcool şi fumatul nu sunt factori de risc pentru infecţia cu *H. pylori*, existând unele păreri că alcoolismul ar avea un efect protector contra infecţiei prin alterarea mucusului gastric (8).

Calea principală de transmitere este cea fecal-orală, de aceea nivelul de dezvoltare economică şi educaţia populaţiei sunt principalii factori de risc pentru infecţia cu *H. pylori*.

PATOGENIE

Caracteristica *H. pylori* este tropismul strict pentru mucoasa gastrică datorită unor antigene de suprafaţă care se fixează de receptorii celulelor epiteliale şi de mucusul gastric, şi capacitatea de a „supravieţui" în mediul acid gastric, ostil altor microorganisme.

Cum reuşeşte *H. pylori* să „supravieţuiască" în mediu acid?

- bacteria secretă o serie de enzime, dintre care un rol major îl are ureaza. Aceasta scindează ureea în CO_2 şi NH_3 care fixează ionii de H^+ din sucul gastric, formând un sistem tampon în jurul *H. pylori*;
- în stadiul iniţial al infecţiei *H. pylori* produce o serie de substanţe care inhibă direct secreţia acidă gastrică (în primele luni de la infecţie pH-ul gastric creşte) urmând ca apoi, în faza cronică să aibă loc o stimulare constantă a secreţiei acide gastrice;
- bacteria se „poziţionează" sub stratul protector de mucus, deasupra celulelor epiteliale gastrice şi la distanţă de sistemul de apărare al mucoasei gastrice, care se găseşte sub lamina propria. Pentru a putea supravieţui însă bacteria are nevoie de nutrienţi care vor fi obţinuţi prin iniţierea unei reacţii inflamatorii, care afectează celulele epiteliale.

În concluzie, deşi infecţia cu *H. pylori* este predominant intraluminală este însoţită de o reacţie inflamatorie cronică, care în lipsa unui tratament va dura toată viaţa. Intensitatea acestui răspuns inflamator de-

pinde de virulenţa bacteriei şi de factorii genetici ai gazdei, ducând la manifestări diferite de boală (11,12).

Factorii de virulenţă

Unele tulpini de *H. pylori* sunt dotate cu o serie de factori de virulenţă, cei mai bine studiaţi fiind : insula de patogenitate cag, proteina vacA, cagA şi genele care codează preteinele membranare.

Insula de patogenitate cag reprezintă un fragment de genom de 40kb ce cuprinde aproximativ 30 de gene care codifică proteine ce asigură un aparat secretor de tip IV (cagE). Acest aparat secretor este folosit de *H. pylori* pentru a transloca în interiorul celulelor epiteliale diverse proteine dintre care cea mai cunoscută este proteina cagA. După translocare, cagA este fosforilată de kinazele Src cu inducerea unui proces de remodelare a celulei („hummingbird phenotype"). Sunt asfel modificate motilitatea şi lungimea celulelor epitaliale gastrice. S-a demonstrat de asemenea că tulpinile de *H. pylori* care conţin mutanţi ai insulei de patogenitate cagA (Hp0524, Hp0540, Hp0542, Hp0543) nu translocă proteina cagA dar induc o secreţie puternică a IL-8, care stimulează motilitatea celulară şi declanşează un răspuns inflamator sever. CagA interacţionează cu sistemele enzimatice celulare cum ar fi tirozin fosfataza SHP-2 (10,11,12).

A fost descris recent un alt *factor de virulenţă – dupA* (duodenal ulcer promoting gene) (jhp0917-jhp0918) – care creşte riscul pentru ulcer duodenal cu reducerea riscului pentru gastrita atrofică şi cancer gastric.

Citotoxina vacA este considerată un factor important de virulenţă în patogeneza ulcerului şi cancerului gastric. Această toxină poate induce multiple modificări celulare : vacuolizarea celulară, formarea de canale membranare, modificări în funcţionarea sistemului endosomal/lisosomal, apoptoză şi imunomodulare. Interacţionează, de asemenea, cu receptorii protein tirozin fosfatazei RPTPß – a căror activare induce vacuolizarea celulară şi fosforilare (Git1). Recent s-a demonstrat că vacA inhibă proliferarea celulelor T, cu blocarea secreţiei de IL-2.

Proteinele membranare sunt codate de o serie de gene ale *H. pylori*, cele descrise ca fiind factori de virulenţă sunt : BabA, SabA, AlpAB şi OipA, BabA, SabA, AlpAB.

SabA este implicată în activarea nonopsonică a neutrofilelor (13).

Modalităţile de răspuns la infecţia cu *H. pylori*

Răspunsul epitelial la infecţie este determinat de mai multe variabile : factorii bacterieni de virulenţă, modalităţile de semnalizare legate de receptorii specifici ce recunosc componente bacteriene şi mediul local reprezentat de hormoni, neurotransmiţători, citokine imune.

Răspunsurile celulelor epiteliale includ :

- modificări ale morfologiei celulare ;
- disrupţia joncţiunilor strânse intercelulare ;
- producerea de citokine ;
- creşterea proliferării celulare ;
- creşterea apoptozei ;
- activarea a numeroase gene asociate stresului inflamator.

În concluzie, infecţia cu *H. pylori* poate îmbrăca diferite aspecte. Cea mai mare parte a subiecţilor infectaţi prezintă doar o gastrită cronică superficială, cu evoluţie benignă, puţin simptomatică, 10% din cei infectaţi dezvoltă boală ulceroasă peptică, aproximativ 1% au o evoluţie spre adenocarcinom gastric şi sub 1% spre limfom MALT.

Funcţie de tipul gazdei (factorul genetic şi răspunsul imun) şi virulenţa bacteriei o parte din cei infectaţi cu *H. pylori* vor avea o evoluţie în ani spre adenocarcinom gastric, în secvenţa : gastrită cronică atrofică (pierderea ţesutului glandular), metaplazie intestinală (înlocuirea celulelor glandulare

cu celule de tip intestinal a căror marker este reprezentat de prezenţa vililor), displazie (apariţia de celule mari, cu atipii nucleare) şi neoplazie.

METODELE DE DIAGNOSTIC ALE INFECŢIEI CU *H. PYLORI*

- metode directe şi indirecte ;
- metode invazive şi non-invazive ;
- tehnici moleculare.

Scopul diagnosticului presupune pe lângă identificare infecţiei, verificare obligatorie a eradicării după tratament şi în cazuri speciale evidenţierea factorilor de virulenţă ai *H. pylori* şi tulpinilor rezistente la claritromicină.

Metodele indirecte – depistează prezenţa răspunsului organismului la infecţia. Cel mai frecvent se utilizează dozarea anticorpilor anti *H. pylori* în ser (metoda serologică). Rezultate fals negative se obţin în „fereastra" imunologică, la taraţi, imunosupresaţi iar cele fals pozitive după eradicarea infecţiei datorită persistenţei anticorpilor ani de zile. Această metodă este utilizată doar pentru diagnosticul infecţiei *H. pylori* şi nu pentru verificarea eardicării.

Cu ajutorul tehnicilor imunoblot se pot identifica şi factorii de virulenţă, respectiv Ac anti cagA, vacA. Prin dozarea gastrinei (G) şi a pepsinogenului (PSG) I şi II în ser se pot obţine informaţii preţioase cu privire la starea mucoasei gastrice (gastrită superficială sau atrofică). PSGI este secretat de celule oxintice din fundus şi corpul gastric, PSGII este secretat în întreg stomacul iar gastrina de celulele G din antrum.

În prezenţa gastritei supeficiale concentraţia serică de G, PSGI şi II creşte, pe când apariţia atrofiei gastrice duce la scăderea concentraţiei serice de G şi PSG, în special cea de PSGI. Raportul PSGI/II reprezintă un indicator important de urmărire a pacienţilor cu Ac anti *H. pylori* pentru depistarea apariţiei atrofiei gastrice (14).

Metodele directe invazive presupun evidenţierea directă a bacteriei sau produşilor de secreţie prin prelevarea de biopsii gastrice şi sunt reprezentate de :

- testul rapid al ureazei ;
- examenul direct al piesei de biopsie ;
- examenul histopatologic ;
- cultura ;
- tehnici PCR în biopsia gastrică.

Pentru evitarea rezultatelor fals negative trebuie luate unele precauţii :

- oprirea tratamentului cu inhibitori ai pompei de protoni (IPP) pentru cel puţin 14 zile ;
- întreruperea tratamentului cu antibiotice ;
- prelevarea biopsiei din regiunea antrală, la 1cm de pilor, de preferinţă 3-4 biopsii şi din corpul gastric la cei cu tratament cronic cu IPP ;
- spălarea sondei de biopsie de glutaraldehidă.

Examenul histologic are avantajul evaluării concomitente a leziunilor mucoasei gastrice, şi reprezintă gold-standardul diagnostic. Se folosesc coloraţiile hematoxilină-eozină, Giemsa modificată, Warthin-Starry. Coloraţia Warthin – Starry este cea mai fidelă, există studii care arată rezultate superioare tehnicilor PCR.

Cultura – este rezervată situaţiilor speciale, când există rezistenţă la tratament, pentru efectuarea antibiogramei. Necesită utilizarea a două medii de cultură, creşterea fiind lentă (7 zile).

Tehnici moleculare – prin tehnici PCR în piesa de biosie se pot depista markerii de virulenţă (vacA, cagA, dupA etc.) precum şi tulpinile rezistente la tratamentul cu macrolide. De asemenea este posibilă depistare *H. pylori* la cei cu limfom gastric MALT. Limita de detecţie a metodei este de 0,02pg Hp (aproximativ 10 organisme).

În concluzie, metodele directe invazive de depistare a *H. pylori* rămân "standardul de aur" al diagnosticului pentru că inventariază în acelaşi timp şi mucoasa gastrică şi permit izolarea bacteriei. Sunt indicate pentru diagnosticul infecţiei şi mai puţin pentru confirmarea eradicării (risc de re-

contaminare) (12,13,14).

Metodele directe neinvazive sunt indicate de elecţie pentru demonstrarea eradicării infecţiei. Prin clearence bacterian se defineşte dispariţia bacteriei după tratament, iar prin eradicare se înţelege dispariţia bacteriei la 4-6 săptămâni de la întreruperea tratamentului.

Există 2 metode directe neinvazive de diagnostic :

- depistarea Ag *H. pylori* fecal ;
- testul respirator cu uree marcată.

Rezultate fals negative se obţin în cazul consumului de IPP şi antibiotice precum şi în cazul gastritei atrofice.

Diagnosticul infecţiei cu *H. pylori* presupune efectuarea unui test indirect (serologic) şi a unuia direct. Infecţia este prezentă dacă cele două teste sunt pozitive şi este absentă dacă cele două teste sunt negative. Un test indirect negativ nu exclude infecţia, deoarece poate apare în infecţia acută şi la imunosupresaţi. Un test direct negativ nu exclude infecţia în prezenţa gastritei atrofice.

TRAMENTUL INFECŢIEI CU *HELICOBACTER PYLORI*

Are drept scop eradicarea infecţiei, ceea ce înseamnă absenţa *H. pylori* la 4-6 săptămâni după terminarea tratamentului, demonstrată, de preferat, printr-o metodă directă neinvazivă (endoscopia are un risc minor de reinfecţie) şi niciodată prin dozarea anticorpilor în ser (se menţin în ser ani, uneori toată viaţa).

Tratamentul standard constă în administrarea a 2 antibiotice şi un IPP cel puţin 7 zile. Metaanalizele recente arată o rată de eradicare sub acest tratament de sub 80%, de aceea, noile protocoale prevăd creşterea duratei de administrare a antibioticului la 10-14 zile, dublarea dozei de IPP, folosirea şi a altor antibiotice, tratamentul secvenţial (12,13).

În România s-a demonstrat o rezistenţă a *H. pylori* la metronidazol de peste 30%, de aceea acesta nu se utilizează în schemele de eradicare de primă intenţie.

Amoxicilina este antibioticul care nu dă rezistenţă, fiind inclusă în toate schemele de tratament.

Pentru a asigura un pH gastric constant ridicat, la care antibioticul să fie activ, se recomandă administrarea IPP în 2 prize. De asemenea, este de preferat ca antibioticul să fie dat în cel puţin în 2 prize (12).

Schema de tratament aplicată de primă intenţie în România constă în IPP (20 mg x 2/zi)+Amoxicilină (1 g x 2/zi)+Claritromicină (0,5 g x 2/zi), 7-14 zile.

Se mai pot utiliza următoarele scheme de tratament :

- IPP 40 mg/zi+ Denol (480 mg/zi) + Amoxicilină (2 g/zi) + Claritromicină (1 g/zi) ;
- IPP 40 mg/zi+ Denol (480 mg/zi) + Claritromicină (1 g/zi) + Tetraciclină (2 g/zi).

O strategie eficientă, relativ nouă, constă în tratamentul secvenţial de eradicare : 5 zile IPP 40 mg/zi + Amoxicilină 2 g/zi, urmate de 5 zile de IPP 40 mg/zi+ Metronidazol 500 mg x 2/zi + Claritromicină 500 mg x 2/zi, cu o rată de eradicare de peste 90%.

În cazurile speciale, cu *H. pylori* rezistent, dificil de eradicat, se recomandă introducerea unui nou antibiotic – Rifabutina 150 mg x 2/zi alături de IPP şi Amoxicilină, 10 zile (14).

Se mai poate recurge, ca tratament de rezervă, şi la combinaţia : IPP + Denol 120 mg x 4/zi +Metronidazol 250 mg x 4/zi+Tetraciclină 500 mg x 4/zi 14 zile, urmat de IPP încă 4 săptămâni.

Pe cine tratăm ?

Consensul de la Maastricht III indică următoarele grupe de pacienţi la care eradicarea infecţiei cu *H. pylori* este obligatorie :

- gastrita cronică atrofică cu metaplazie intestinală ;
- ulcerul duodenal şi gastric ;
- gastrita *H. pylori* pe bontul gastric după neoplasm gastric ;

- antecedentele heredecolaterale de cancer gastric ;
- limfomul MALT cu grad scăzut ;
- la cererea pacientului, după consultarea medicului curant.

Marea majoritate a pacienţilor infectaţi nu au indicaţii absolute de eradicare. Avantajul eradicărării ar fi scăderea rezervorului de bacterii şi împiedicarea evoluţiei spre gastrită cronică atrofică, stadiu în care eradicarea se face greu datorită scăderii numărului de colonii. Studiile recente arată că eradicarea infecţiei cu *H. pylori* în stadiile avansate de atrofie gastrică nu scade riscul de cancer gastric.

În practică se aplică eradicarea *H. pylori* la toţi pacienţii cu ulcer peptic (eradicarea „vindecă" ulcerul şi duce la dispariţia recidivei), la pacienţii cu infecţie pe bont gastric după chirurgia pentru neoplasm, la pacienţii cu limfom MALT şi la toţi pacienţii cu gastrită, simptomatici sau nu, dacă aceştia doresc.

Marele „dezavantaj" al eradicării „în masă" este reprezentat de selectarea tulpinilor de *H.pylori* rezistente. De altfel pentru România este demonstrată rezistenţa *H. pylori* la Metronidazol (utilizat foarte mult pentru tratamentul lambliazei şi în infecţiile genitale). S-a dovedit că la pacienţii cu boală de reflux gastro-esofagin întreruperea tratamentului cu IPP nu este urmată de rebound acid dacă există infecţie cu *H. pylori*.

CONCLUZII

H. pylori este bacteria care dă cea mai frecventă infecţie cronică la om din lume. Prin mecanisme specifice reuşeşte să „supravieţuiască" în mediu acid gastric. Tipul de inflamaţie depinde de factorul genetic şi de virulenţa bacteriei. Majoritatea celor infectaţi prezintă doar o gastrită cronică superficială, fără riscuri majore. Doar 1% din subiecţii infectaţi dezvoltă adenocarcinom gastric în secvenţa gastrită cronică atrofică-metaplazie intestinală- adenocarcinom. Tratamentul se face cu triplă terapie, scopul fiind eradicarea infecţiei. Se preconizează scăderea „rezervorului" uman de bacterii „preţul" fiind selectarea tulpinilor rezistente.

CARDIOMYOPATHY IN LIVER CIRRHOSIS – AN UNDIAGNOSED ENTITY ? (Abstract) : Cirrhotic cardiomyopathy is a condition recently known in liver cirrhosis consisting of systolic dysfunction to stress factors, diastolic dysfunction and electrophysiological abnormalities in the absence of cardiac disease. The prevalence of cirrhotic cardiomyopathy remains unknown until now. It can be diagnosed by using a combination of electrocardiograph, 2-dimensional echocardiography, and various serum markers (brain natriuretic factor - BNP, proBNP, TnI). Pathogenic mechanisms underlying cirrhotic cardiomyopathy development include abnormal signaling βadrenergic, cardiomyocites membrane fluidity changes, interstitial fibrosis, myocardial hypertrophy, altered transmembrane ion channels as intervention with negative inotropic effect of different substances whose concentration is increased in cirrhosis. Major stresses on the cardiovasculary system such as liver transplantations, infections, insertion of transjugular portosystemic stent-shunt (TIPSS) have been demonstrated to put in evidence the presence of cirrhotic cardiomyopathy. Heart failure is a significant cause of mortality after liver transplantation but the improvement of liver function determines cardiac abnormalities reversal. Current management recommendations include empirical, nonspecific and mainly supportive measures, no specific treatment can be recommended, and cardiac failure should be treated as in non-cirrhotic patients with sodium restriction, diuretics, and oxygen therapy when necessary. The exact prognosis remains unclear. The extent of cirrhotic cardiomyopathy generally correlates to the degree of liver insufficiency. Reversibility is possible (either pharmacological or after liver transplantation), but further studies are needed. **Key words** : CIRRHOSIS, CARDIOMYOPATHY, DIASTOLIC DYSFUNCTION, SYSTOLIC INCOMPETENCE, QT INTERVAL

EDITORIAL

KEEPING AN OPEN MIND ON LONG-TERM USE OF PROTON PUMP INHIBITORS

Since the release of omeprazole, the first proton pump inhibitor (PPI), in 1988 in Europe and, two years later, in the United States, six other PPIs have become available such as pantoprazole, esomeprazole, lansoprazole, dexlansoprazole, and rabeprazole. The discovery of omeprazole is the story of a huge therapeutic success, the result of over 20 years of hard work and meticulous research made by an extraordinary team of more than 150 researchers, who discovered and tested over 800 compounds, surmounting unimaginable obstacles.

Once introduced in the clinical practice, PPIs have revolutionized the management of acid-related diseases such as peptic gastric/duodenal ulcer (including bleeding peptic ulcer), gastroesophageal reflux disease, Helicobacter pylori (in combination with antibiotics), Zollinger-Ellison syndrome, being later recommended for the prophylaxis of upper gastrointestinal complications with nonsteroidal anti-inflammatory drugs therapy, in ICU prophylaxis for stress ulcer as well as in functional dyspepsia. Thus, PPIs have become some of the most widely prescribed agents throughout the world, with tens of billions of US dollars in global sales. Still, their use and sales are continuously increasing due to their efficacy and safety profile when administered according to the appropriate indications. Unfortunately, the use of PPIs outside their area of recommendation has increased alarmingly over the past decade, particularly in the more recent years, because them being available as over-the-counter medication in many countries, Romania included.

During almost three decades of clinical use, PPIs proved to be an efficient and safe group of drugs, with enormous benefits for millions and millions of people when used for well-established indications. Several studies found that the adverse effects occurring under PPI therapy are like those of placebo, while a study on the efficacy, tolerability and safety of up to 15 years' continuous maintenance treatment in severe acid-peptic disease reported no safety concerns (1).

Nevertheless, there is no pharmaceutical agent approved in clinical practice that does not carry a certain degree of risk. Even placebos, used in clinical trials for comparison with new drugs in terms of "safety", may have some adverse effects. Like in case of other drugs, PPIs are not always as safe as it has been thought, and concerns were raised about their potential association with several and serious adverse events, ranging from bone fractures (2) and community acquired pneumonia (3) to acute myocardial infarction (4) and inpatient death (5). It should be underlined that all studies regarding the association of PPI therapy with the risk for developing the above mentioned adverse events are supported mostly by observational research, and therefore, cannot confirm causality. The scientific strength of all observational studies is weak (odds ratio < 2), while most are retrospective and some are case reports

or case series. The quality of evidence regarding potential association with PPI therapy is consistently low to very low. Recently, in an excellent three review articles, experts critically analyzed the published literature about the potential adverse events associated with the long-term use of PPIs (6-8).

An association between PPI therapy and increased risk of bone fracture is based on several mechanisms such as reduced calcium absorption secondary to increased intragastrical pH levels induced by PPIs, but current evidence suggests a very weak connection (OR 1.24) (2). Moreover, the link between PPIs use and increased fracture risk has not been consistently demonstrated.

PPI therapy has also been associated with increased risk for community acquired pneumonia (3). The underlying mechanism of such an association remains unknown, although some researchers have suggested that PPI-induced low gastric acid secretion may lead to bacterial overgrowth in the stomach and from there, by an "upstream" effect, reach the oropharynx and then the upper airways. Overall, the association between PPI therapy and community-acquired pneumonia remains controversial, and clinicians should not refrain from prescribing PPIs, when indicated.

Cases of acute interstitial nephritis associated with PPIs use have been reported ever since the early 90s. Recently, one study reported that PPI users presented a significantly higher risk of chronic kidney disease probably due to recurrent episodes of acute nephritis (9), but such a connection is weak and remains uncertain.

Reduced gastric acidity with prolonged PPI therapy may interfere with the absorption of calcium, magnesium, iron, vitamin B12, and several cases of hypomagnesemia, hypocalcemia, iron deficiency anemia, and vitamin B12 deficiency have been reported (10). Nevertheless, data regarding an association between PPI therapy and micronutrient deficiencies are inconsistent and highly controversial.

Although several studies, systematic reviews, and meta-analyses (11, 12) reported an association between PPI use and the risk for *Clostridium difficile* infection (CDI) development, such a connection remains controversial as all the studies which support it are observational, with inherent accuracy limitations and significant heterogeneity as well as evidence of publication bias. In addition to this, most of the studies reporting associations between PPI use and the risk for CDI have a very low-quality evidence, not supporting a cause-effect relationship, while other studies failed to find such an association.

Observational studies have reported a link between PPI use and the risk for hepatic encephalopathy in a dose dependent manner (risk increases with dose) (13) or spontaneous bacterial peritonitis in cirrhotic patients (14), but the quality of evidence is low such connections are inconsistent and controversial.

More recently, several other associations between PPI therapy and serious adverse events such as dementia (15-17), stroke (18), acute myocardial infarction (4), and even inpatient death (5) have been reported. Thus, two clinical studies (15, 16) have shown that PPI use was associated with a 38% and 44%, respectively, increased risk for dementia. Such possible association caught great attention from the clinicians, considering the high prevalence (millions of patients) and economic impact (billions of US dollars) of this disease. There are two

suggested mechanisms linking PPIs to the development of dementia: vitamin B12 deficiency and enhanced brain beta-amyloid levels (17). However, the two-mentioned study (15, 16) present many limitations such as the lack of adjustments for some important risk factors for dementia (e.g., alcohol use, hypertension, family history of dementia). Thus, we do not have a clear evidence regarding an association between PPI use and the risk for dementia. Consequently, physicians should prescribe PPIs when the indication is well-established.

An increased risk of adverse cardiovascular events associated with PPI therapy have been reported by several studies. Recently, one study found that PPIs use is associated with the risk of first-time ischemic stroke in the general population (18). As with others retrospective observational studies, the strength of this association is low and a cause-effect relationship.

Several studies have suggested a potential association between PPIs use and the risk for myocardial infarction (4, 19). A leading hypothesis to explain such a risk is based on observational studies which showed that concomitant use of PPI and clopidogrel was associated with an increased risk of recurrent post-acute coronary syndrome. Ex vivo analyses suggested that PPIs competitively inhibit hepatic cytochrome P450 isoenzyme 2C19C (CYP2C19) necessary to metabolize clopidogrel in its active form and thus, increasing the possibility of clot formation and the risk of coronary thrombosis. Shah et al (4) reported a modest association between long-term PPI therapy and the risk of myocardial infarction in the general population. Nevertheless, all the studies regarding a potential association between PPI therapy and the risk of myocardial infarction are retrospective observational, and therefore cannot demonstrate a causal relationship.

PPI therapy has also been linked to a potential risk for gastrointestinal malignancies by causing hypergastrinemia which facilitates gastric colonization by *Helicobacter pylori* and stimulate hyperplasia of enterochromaffin-like cells leading to development of gastric neuroendocrine tumors (NETs). Nevertheless, large clinical studies have not confirmed an association between PPI therapy and gastric cancer or gastric NETs (20). Prolonged use of PPIs (more than 2 years) increased the risk of fundic gland polyps (21) which are not premalignant lesions.

Finally, a study just published reported excess risk of death among PPI users (5), among patients without gastrointestinal comorbidities; risk is also increased with prolonged duration of PPIs use. The mechanism of association between PPI use and risk of death remains unknown. Most probably, the occurrence of any of the adverse events associated with PPI long-term therapy mentioned previously (e.g., kidney disease) contributes to excess risk of mortality. This study is a retrospective, observational with known limitations, and therefore, further studies are needed to evaluate the association between PPI use and the risk of all-cause mortality.

All these studies mentioned above, reporting several adverse events of PPI use may create alarmism among physicians and spread fear among the informed patients, some of whom declining PPI therapy even when they have clear indications. The media also contributes to maintaining a state of panic among PPI users, with pessimist headlines such as “Heartburn pills hike stroke risk by 90%” (*Sun*, November 16,

2016). Despite such warnings, PPIs continue to be considered by most physicians as "safe" drugs, providing immense benefits when prescribed for appropriate indications. However, PPIs are widely used by millions of people for indications that were never approved.

As current evidence cannot confirm causality between PPI therapy and the risk for developing any of several above mentioned serious adverse events, a final estimation of the real risk is not possible. Yet, the existence of the risk for some adverse events of long-term PPIs therapy cannot be overlooked, and clinicians should be aware of them, and should inform their patients on such a risk, without, however, refraining from prescribing PPIs at the lowest effective dose and for shortest possible time only for clearly established indications.

EDITORIAL

REFUSAL TO VACCINATE AND FALSE HYPOTHESES *VERSUS* NEW HYPOTHESES

Starting from February 2016, Romania faces an ample epidemic wave of measles, with 9760 cases and 35 deaths. Most of the cases affected children, mainly because of the refusal to vaccinate (1).

The expansion of the population's anti-vaccination attitude mostly occurred after 1998, when Andrew Wakefield published an article in The Lancet, suggesting as explanation for autism, the MMR (measles, mumps, rubella) vaccination which would inflammatory bowel disease, as a first stage that would determine the subsequent translocation of intestinal flora, followed by dissemination in blood, and brain lesion. Although the paper was based on the investigation of digestive manifestations associated with neurological disorders made on a study group of 12 children, of which 8 had been vaccinated against MMR and one had had measles, the conclusion, namely the association between autism and MMR vaccination, made the population refuse this vaccine (2). Later, multiple studies, starting with the one published in the same famous magazine in 1999 (3) brought strong scientific arguments to shake A. Wakefield's fake hypothesis. From then, even if The Lancet's editors retracted the quoted paper which generated among people the fear that MMR vaccine induces autism, the refusal to vaccinate phenomenon persisted, also comprising other types of vaccines. The data gathered to support the fight against Wakefield's hypothesis were synthesized by *Immunization Action Coalition* that listed 26 scientific papers (4). These rigorous studies argumentatively fight against erroneous assertions that explained the anti-vaccination trend but, obviously, they had no impact on the general population, at least in Romania, most probably caused by the lack of strategies of the Ministry of Health regarding the communication of scientific information, in a language that is accessible to general population. Obviously, the anti-vaccination group is more vocal, and its actions had a higher impact on the general population than the information and support campaigns meant to lead to vaccination acceptance supported by specialists.

If, initially, the relation between the MMR vaccine and autism was connected to the dysbiosis induced by the vaccine at the level of intestinal microbiome, the arguments that currently support the mechanisms that are responsible for the installation of autism spectrum disorders (ASD) are also correlated to microbiome, but with no implication of the vaccine as a trigger.

The new molecular biology methods used inclusively to characterize the human genetic luggage were refined, including for the study of microbiome, especially those at the intestine level, as it represents 70% of the 100 trillion microorganisms (bacteria, viruses, fungi, archaea) that constitute it. The evaluations in the human genome catalogue shows we have about 22,000 de genes, but as "non-redundant" genes - 3.3 million, in human intestinal microbiomes. The diversity among individuals' microbiomes is impressive: human is approximate-

ly 99.9% identical as regards their genome but, usually, as regards each of their microbiomes, the differences reach 80% to 90% (5).

Metagenomics and metatransriptomics studies allowed the description of 3 enterotypes at the level of the intestinal microbiome. An enterotype is a classification of living organisms based on its bacteriologic ecosystem, in intestinal microbiomes. The discovery of three human enterotypes was announced in 2011 by the research collective coordinated by Peer Bork. These enterotypes are not regulated by age, gender, weight or nationality. But there are indices showing that long term diet influences the enterotype. Type 1 is characterized by high levels of *Bacteroides*, type 2 by *Prevotella* and type 3 has high levels of *Ruminococcus* (6).

We do not know for sure which is the physiological role played by these enterotypes (eventually in inducing different conditions), but during the last years, different studies signaled the modification of the microbiome predominated by genuses and species associated to disease conditions (from metabolic diseases to celiac disease, Crohn's disease, ulcerative colitis, irritable bowel syndrome, obesity, non-alcoholic fatty liver, type 1 or 2 diabetes, to infectious diseases - *C. difficile* associated infections, translocation of *Enterococcus* resistant to vancomycin, to the chronic fatigue syndrome, thyroid dysfunctions, rheumatoid arthritis, ankylosing spondylitis, eczema, asthma and even ASD (as well as other neuropsychiatric disorders like depression) (7).

Some studies already bring arguments regarding the modifications of microbiome in different pathologies. For example, by sequence of some components of the intestine microbiota, (8) showed that in patients with acute diarrheal disease (ADD), the quantity of *E. coli* is higher, in comparison with healthy people, like after the ADD cure. The most frequent etiological agents mentioned in this study were the following: *Salmonella*, *E. coli* Shiga-like strains, *Campylobacter* and *Shigella* toxin producer, together with the quantitative increase of commensal *E. coli*. The study proposes to reconsider therapy, so that to control the quantity of *Escherichia* in cases of severe diarrhea and/or to promote the development of microbial populations, which are important for the good functioning of the healthy intestine. The results of the quoted study came from DNA sequencing from microbes at the intestine level in persons with diarrheic diseases caused by these four pathogen agents. Then, they compared the results with the microbes founded in healthy members of their family. As expected, the intestinal microbial communities differed in case of healthy and sick persons. On the other hand, the microbiota composition in patients with ADD was similar indifferently from the isolated etiological agent. Moreover, patients with similar specific profiles of the microbial community had a more severe disease and these modifications were similar, indifferently from age, gender or race. Future researches based on these discoveries should reconsider therapy strategies that involve probiotics or anti-microbial agents regarding the development of benefic microbes and fast decrease of proteobacteria populations, a major group of bacteria including several pathogen agents, like *Escherichia*. Such strategies could decrease the potential of intestinal infections and would facilitate the faster recoveries of those affected by ADD (8).

During the last years, studies based on

proving "intestinal-ADD microbiome" causality underlined the need to clarify pathogenic mechanisms as well as the concern about the explosive growth of the number of cases, namely from one case of 5000 children, to a case of 68 children (9). Per genders, boys are obviously more affected, about 1 case of 40 children for boys, and 1 case of 190 for girls, therefore a gender report of about four-five boys for each girl (10) Most probably, the signaled growth could be the consequence of specialists' concern on ASD, as well as on the new diagnosis criteria, not necessarily by a real growth of the number of cases, therefore an epidemic manifestation as initially thought. Of course, during the last years, the contribution of certain co-factors (including the environmental factors, antibiotics therapy and unbalanced diets etc.) also amplified, among which the most important role seems to be played by the constellation of intestinal microbiome (also modified because of the above-mentioned factors) (9).

The autism spectrum disorder (ASD) is defined as a set of neurologic development disorders, characterized by two types of main manifestations: social deficit and exacerbation of repetitive/stereotype behaviors. Together with the basic symptoms of ASD, different authors also noticed other comorbid conditions in some of the ASD patients, like gastric-intestinal complications (GI) and modifications of the intestinal microbiome (11, 12).

The relation between intestinal microbiome and ASD was suggested by the multitude of digestive symptomatology signaled in patients with ASD, namely, constipation or diarrhea or gastric acidity reflux. The brain - intestine - microbiome axis refers to interactions between the central nervous system, the gastrointestinal system and microorganisms from the gastrointestinal tract. The exploration of these interactions offers an explanation why gastrointestinal disorders are frequently met in children with ASD. The signs of brain-intestine affection are strongly related to functional disorders at the GI level that are frequently met in children with ASD. Studies on the microbiome in children with ASD suggest the intestinal microbiome modifications can be associated with ASD and gastrointestinal disorders in case of these children. But the data collected until present day are insufficient, so future studies are needed about the brain-intestine-microbiome axis, which could lead to new techniques meant to identify GI disorders in ASD children, as well as new therapies of the disorders accompanying this syndrome (13).

Emergent studies on the intestine-brain interaction indicate that the modifications of this axis can play a regulating role on the health condition, as well as in inducing certain conditions, including the ASD. Studies on real causes of the GI conditions in children are limited. A study that prospectively evaluated the possible causes of GI in children with ASD indicates that most of this symptomatology is not due to physiological or organic causes, but to functional causes (14).

Gorrindo et al., quoted by Luna et al. analyzed a group of 121 children, subsequently divided into 3 groups: ASD and GI disorders children, ASD children with no association of GI manifestations and children with GI manifestations and no ASD. The evaluation made of pediatrics gastroenterologists for the 2 groups of children with GI manifestations discovered that the functional gastrointestinal disorders (FGID) represent the most frequent cause

of GI accuses in both lots of patients. In the ASD group, 37 of the 40 children were diagnosed with FGID. Functional constipation was the most frequent GI disorder in this group. These findings correspond to the hypothesis according to which GID in ASD represent the pleiotropic expression of genetic risk factors, therefore medicines and diet do not influence the GI manifestations (13).

The practical recommendations and conclusions of other specialists in pediatrics continue to claim that most of the GI symptoms in children with ASD are due to functional disorders like those observed in children with neurotypical development and not to some physiological condition unique for ASD. The different studies that analyzed the influence of microbiome on ASD evolution concluded there was a definite relationship between the different types of intestinal microbiome and ASD, namely the association between the increase of the quantity of *Lactobacillus* and the decrease of the quantity of *Bifidobacterium* in feces (11). On the other hand, there are discordant results regarding the level of short chain fatty acids (SCFAs). According to some authors, this level is low, according to others, it is high. Thus, the low level of SCFAs (ex. acetate, propionate, valerate) was partially associated with children with ASD, with a high probiotics supply and, probably, partially due to a lower production (because of a lower sugar fermentation of benefic bacteria and/or low fiber supply) and/or higher absorption in the organism (due to a longer transit and/or due to a high intestinal permeability) (11).

Other authors (16) ascertains that the SCFAs elimination of feces is higher in children with ASD, but certain fatty acids (e.g. acetic, butyric, isobutyric) were high and caproic acid was high too. If the profile of colon microbiota would be identical in all children with ASD, we could identify those common markers present in most of the children with ASD, so that by finding it in feces and replacing the determination of the colon microbiota (implying sophisticated and expensive metagenomic and metaproteomic tests) highlighting these markers.

Unfortunately the intestinal microbiome profile differs from one individual to another with more than 50% (even 80-90% according to some authors), therefore it would be difficult for us to identify the most common profile of intestinal microbiome associated to ASD, so that prebiotics and/or probiotics adjuvant therapy would regulate the microbiome profile, encouraging benefic bacteria (e.g. *Bifidobacterium*) and discouraging the multiplication of dangerous bacteria (most probably associated to dysbiosis typically associated to ASD (e.g. *Clostridium*) (15).

In comparison with the intestinal microbiome in children without ASD, the intestinal microbiota in children with ASD is less diverse and it presents lower levels of *Bifidobacterium* and *Firmicutes* and higher quantities of *Lactobacillus, Clostridium, Bacteroidetes, Desulfovibrio, Caloramator* and *Sarcina* (11, 15). In children with autism presenting GI symptoms lower quantities of the following bacteria were found: *Prevotella, Coprococcus* and Veillonellaceae not classified, except that found in children with no GI symptoms. The fecal samples in children with ASD also have higher levels of the *Clostridium histolyticum* group (Clostridium, clusters II and I), in comparison with samples from healthy animals with no connection to children (12). On the other hand, in case of children brothers with GID, without au-

tism, they present an intermediary level of *Clostridium histolyticum* that do not significantly differ from the group of ASD children. *Clostridium* can produce neurotoxins and it could exercise systemic effects (12). The reduction of clostridia upon the administration of vancomycin has a benefic effect on the evolution of children with ASD (16), (17). Moreover, children with ASD present modifications of the levels of *Bifidobacterium*, *Prevotella* and *Sutterella*. As we already know, the intestinal microbiota in newborn differs according to the type of birth; in case of natural births we deal with *Lactobacillus*, while in case of C-section births, we deal with *Staphylococcus* and *Propionibacterium* and we noticed that C-section babies present a 20% higher risk to develop ASD (18). Still, the association did not persist when the control group used is that of the brothers of these children; this is the reason why we suppose genetic and/or environmental factors also interfere (18). Nowadays, it is unanimously accepted that both genetic and environmental factors are involved in the etiopathogenesis of the so-called non-syndromic ASD, which is not a side effect of a well-known genetic condition. For a long time, the percentage of the genetic element was essential but during the last years, considering the dramatic growth of ASD prevalence, the role of environmental factors gained a relatively greater importance. Beside these obviously epidemiologic considerations, as suggested by Wong et all, the hypothesis according to which exposure to the environmental factors can considerably contribute to ASD development is supported by the presence of different sub-sets of candidate genes, distinguished in each ASD subject and by a high phenotypic variability of these individuals. Despite this, there is still more to discover about the complex interaction between these causal factors. The relatively new concept of epigenetics can be very useful from this point of view at least for certain ASD cases. Epigenetics represents a fundamental regulation mechanism of the gene based on chemical modifications of the DNA proteins and histone, without changing the DNA sequence. It was proposed for the environmental factors like heavy metals and endocrine disrupting chemicals to be able to modify the epigenetic condition and genic expression, leading to ASD (19).

A recent synthesis tried to identify the environmental factors that could play a decisive role in ASD etiopathogenesis, counting air population, including perinatal and postnatal population, exposure to heavy metals (mercury, plumb, and arsenic), pesticides, nitric oxides, electromagnetic pollution or polyunsaturated fatty acids. Despite the critical analysis of numerous studies on this subject, authors could not reach to a clear conclusion on the role of environmental factors in inducing ASD, so they proposed to continue with these studies; future researches should investigate this relationship and bring solid proofs to certainly conclude on the significant difference in ASD prevalence in countries with high pollution levels *versus* those with low pollution levels (19, 20). We still have no information on the cause of digestive disorders in some of the children with autism. A co-factor that seems to influence the occurrence of ASD is the excessive use of oral antibiotics, which could also translate a deficit in immune defense in case of these children. The antibiotics therapies, especially those of broad spectrum, practically destroy normal flora, which is so useful in regulating intestinal functions,

including its motility and fluids contribution, breakdown of some vegetal polysaccharides, production of vitamins and competition against colon colonization with pathogen bacteria (11). The administration of certain antibiotics and probiotics (like fermented milk containing *Lactobacillus* strains, temporarily improves digestive symptoms, as well as symptoms associated to autism (21). The strong correlation between gastrointestinal symptoms and autism severity indicates that children with more severe types of autism present more severe gastrointestinal types of autism and *vice versa*. It is possible that autism symptoms would be amplified or even partially due to gastrointestinal issues. In a relatively recent study, in case of the autistic children, it was determined a low SCFAs level, partly associated with the use of probiotics, low level of sugar fermentation because of benefic bacteria that are practically absent or with the reduced contribution of soluble fibers, long transit and/or due to a high permeability at the intestine level.

CONCLUSIONS

Even if the ASD etiopathogenesis is not completely elucidated, it is evident from the studies conducted so far that this disorder is not induced by the MMR vaccine and that the intervention of several cofactors (genetic, environmental and especially of the intestinal microbiome) is responsible for ASD installation, which affect more and more children during the last years. Until the future studies are to be completed, the gathered data regarding this mechanism, especially about the intestine - brain axis and gut microbiome, we can claim that MMR vaccination, represents the most redoubtable weapon of the humanity, meant to prevent and fight against a dangerous disease.

ANATOMY AT THE IASI FACULTY OF MEDICINE: SCIENCE, SUBJECT OF STUDY AND CONCEPT

Grigore T. Popa, in a memorable inaugural lecture entitled *What Does and What Doesn`t Anatomy Mean* (1928), summarizes a period of teaching and research, and traces the future of this subject of study and concept at the Faculty of Medicine of Iasi: `*No structure can be fully understood unless its reasons of occurrence, presence, and functional justification are obvious and able to explain its development and way to perfection. To list and describe the hand muscles is valueless unless the undergraduate can interpret the movements of the hand with which every day he washes his face*`. Our brief history has in view the long road to this concept of the Iasi school of Anatomy.

The first attempts at founding a medical institution of higher learning in the Romanian Principalities occurred in the first decades of the 19th century. Two such institutions are worth mentioning in this brief outline: N. Kretulescu's School of Elementary Surgery founded in Bucharest in 1842, and Neculai Negură's School of Surgery, started in Iasi in 1859. The former, although an institution of secondary education, played a key role in the foundation of the Faculty of Medicine in Bucharest in 1869. The latter was initiated by Neculai Negura, a graduate of the Faculty of Medicine from Berlin. Moreover, N. Negura`s school was the first academic medical school in Romania in which all courses were taught in Romanian. Unfortunately, its existence was ephemeral. The school had a brief existence as its initiator could not face the many difficulties encountered at the beginning. The same situation occurred when the University of Iasi was founded in 1860. De facto, the Faculty of Medicine was not among the four initial faculties of the oldest university in Romania. The Faculty of Medicine of Iasi was started only in 1879. On September 27, 1879, Nicolae Kretulescu, the then Minister of Public Education, signed the decree no. 11389 in which he approved the foundation of the Faculty of Medicine at the University of Iasi. Several days later, Prof. Petru Suciu, the Rector of the University of Iasi, to meet the demands of the minister`s decree, convened several meetings that took place on September 30, October 2and 5. Since 1879, the Faculty of Medicine of Iasi has been functioning without interruption. However, the existence of the new Faculty of Medicine depended on the quality of the teaching staff. In this respect, the Academic Council of the University recommended dr. Gh. Iuliano for the course of lectures in Descriptive Anatomy and Histology, and chemist Petru Poni for the Chemistry course. Both were recommended as substitute instructors. In his turn, dr. Telemac was recommended for the position of prosector. Despite this, the minister did not consider the local decision and appointed dr. Leon Scully for the course of lectures in Anatomy and Histology and pharmacist S. Konya for the course of lectures in Chemistry. Only the appointment of dr. Telemac as prosector was approved by the minister. With this initial teaching staff, the Iasi

Faculty of Medicine began its activity. At that stage, the Faculty enrolled only 14 students. The initial syllabus, received from Bucharest, was identical with the one used by the University of Bucharest. Two rooms in the University building were assigned for the courses of the Faculty of Medicine. The first Anatomy lecture was given by dr. Leon Scully. He also became the first dean of the Iasi Faculty of Medicine. He was appointed professor of anatomy in 1879 and two years later professor of surgery.

Dr. **Leon Scully** was born in 1853 in Piatra Neamt. He graduated from the University of Montpellier, where he obtained his degree in Medicine. He furthered his education at the Faculty of Medicine in Paris where he passed his PhD degree. At the time he gave his first lecture he was only 26 years old. In 1881, he was transferred to the position of Chair of the Clinical Surgery Department, a place he held until his death in 1912. Despite the various hardships and hostile attitudes, the Faculty of Medicine flourished. In the 1880-1881 academic year, the Faculty of Medicine was attended by undergraduates in the 1st and 2nd year of studies. The syllabus was enriched with new topics and new substitute instructors were appointed to the newly established departments. In the coming years, several new students were enrolled. The teaching programs were improved and the number of instructors increased. There were many signs at the time that the Faculty of Medicine had strengthened. More young doctors, graduates from Paris and Vienna, were employed during this time as substitute members of the teaching staff. Since 1884, following the graduation exam, the first series of doctors in Medicine and Surgery from Iasi left this institution of higher education. Starting from that year, the growing number of graduates reflected the stability and prestige of the institution. During that period, the Department of Descriptive Anatomy was provided with important teaching materials making it able to better train a substantial number of excellent specialists even from the first decade of activity of this faculty.

Nevertheless, the true founder of the School of Anatomy of Iasi was Professor **Aristide Peride**, who dedicated his entire activity to the organization of education in Anatomy at the Iasi Faculty of Medicine. Aristide Peride was appointed as a substitute professor in Anatomy in 1881. In 1889, he became a full professor. Professor Peride (1848 – 1906) linked his name with the construction and organization of the Institute of Anatomy, a remarkable structure which exceeded many similar institutes in this part of Europe. The newspapers of the time have long commented on this outstanding accomplishment. In this respect, the following "chronicle" in the "Hospital" (1890) gave interesting details: "*In a few days the building of the Institute of Anatomy, part of the Faculty of Medicine, will start in Iasi. The new building will be in the courtyard of the University building. When the work on the new building of the University will have been finished, it will serve as premises for the Faculty of Medicine. The architect of the new building is Prof. Stef. Emilian. We also learnt that the Ministry of Public Instruction commissioned the famous French sculptor W. Hegel, author of the beautiful statue of Miron Costin in Iasi and of other works, to create a large bas-relief of several meters, which will serve as a frontispiece to the Institute of Anatomy. The French sculptor will represent on the bas-*

relief the first lesson on the circulation of blood given by Harvey. The beauty of the work that will decorate one of the famous buildings of the University of Iasi is guaranteed by the name of the sculptor."

Provided with rooms for dissection and experimental surgery, an anatomical museum, annexes necessary to laboratory preparations, a library and an amphitheater, the Institute of Anatomy has ensured the training of many generations of students of the Faculty. Professor Peride himself contributed to the endowment of the museum collection of the institute. He identified himself, for a prolonged period (1881 and 1906), with the department he created. The department of Descriptive Anatomy, set up by Aristide Peride, who held the chair until 1906, was subsequently represented by two outstanding professors: **Ion Tanasescu** (1907-1913) and **Francisc Rainer** (1913-1919).

Ion Tanasescu was born in1875 in Fălticeni. He graduated from the Faculty of Medicine in Iasi in 1902 with the PhD thesis "General considerations on hydrocele and its treatment." While for a period of specialization in Paris, he worked for three years in the anatomy laboratory of Professor Poirier and three years in the surgery service run by Professor Hartmann. He returned to his native country in 1907, after graduating with honors in Anatomy, where he became Professor Leon Scully`s assistant. In 1908, he won the competitive exam for the chair of the Anatomy Department at the Faculty of Medicine in Iasi, where he became the 2nd professor, being promoted to a full professorship in 1913. In 1913, he was transferred to the Department of Topographic Anatomy and Surgery. Ion Tănăsescu was especially known as professor of Surgery. But Professor Tănăsescu was also an accomplished anatomist, combining erudition with exceptional surgical skills. He published important studies, especially on lymphatic vessels, cited in the classic European treatises. Prof I. Tănăsescu is the founder of modern surgery and functional anatomy at the Iasi University of Medicine. He was also the ``father`` of the Palace of Surgical Clinics, the most modern structure of this kind in South – Eastern Europe at the time.

Since 1900 the surgery school in Iasi has greatly developed and included the departments of External Pathology, Topographic Anatomy, Surgical Medicine, the surgical clinics and the specialized surgical clinics (Obstetrics and Gynecology, Genitourinary, Ophthalmology). The extension of the surgical school of Iasi was also due to the contribution of celebrated surgeons and great anatomists, such as Ernest Juvara and Ion Tănăsescu.

In 1898, Professor **Ernest Juvara** became a full professor at the Topographic Anatomy Department. In 1903, this department had to merge with the Surgery Clinics department, similarly to the counterpart department in Bucharest led by Prof. Toma Ionescu. **Ernest Juvara** (1870-1933) was born in Bârlad, in a wealthy family. In 1889, he started the medical studies at the Faculty of Medicine of Paris, where he worked in the chemistry laboratory of Professor Gauthier, then in the anatomy laboratory headed by Professor Poirier. In the laboratory of Profesor Poirier, Ernest Juvara wrote Poirier's lessons *"Quinze leçons d'anatomie pratique"* complemented by many original illustrations, a work published in five editions, also translated into German. Initially, he had the right as an undergraduate student to work in the hospitals of Paris, then he

headed the laboratory of Professor Poirier, and as instructor he worked in the pathological anatomy laboratory of Professor Duplay's surgical clinic. In 1895 he passed his PhD, at the age of 28. At this age Ernest Juvara passed an exam and was appointed as the 2nd professor in the Topographic Anatomy department of Iasi, where he was recognized as an anatomist of great learning and precision in the execution of drawings and anatomical preparations and as an accomplished surgeon. Some of the anatomical drawings made by Professor Juvara and some sections and anatomical parts he made are kept in the Museum of the Institute of Anatomy in Iasi, highlighting his skills. In 1912 Professor Juvara was transferred to Bucharest, where he headed the clinics at Filantropia and Brancovenesc hospitals. In 1906, he founded the 1st Clinic of Surgery at St. Spiridon Hospital of Iasi as a special surgical teaching unit.

Between 1913 and 1920, the Descriptive Anatomy Department was led by Francisc Rainer. **Francisc Rainer** (1874 – 1944), born in Bucovina (Rehozna) graduated from the secondary school and the Faculty of Medicine in Bucharest. He worked for a long period of time as head of the laboratory of Colţea Hospital. In 1913, he began his teaching career, as he became the Head of the Descriptive Anatomy Department in Iasi.

Professor Francisc Rainer's personality was many-sided. However, the greatest merit is the fact that he innovated the concept of Anatomy as a subject of study. He introduced, among the first in the world, the concept that Anatomy is the study of living, dynamic forms. The concept of functional biology opened men vistas to the interpretation of Anatomy overcoming the cumulative, strictly analytical study. Such an approach was a novelty for that period. Later, this concept was accepted by all specialists in the field. The transition of anatomy from a static, descriptive position to a biological interpretative position determined indirectly the new status of Anatomy among the other branches of Biology. Prof. Fr. Rainer was careful enough to place at the entrance to the dissection hall of the Institute of Anatomy the following words: *Anatomy, the science of living forms*. This statement is the essence of his scientific creed. When he left for Bucharest, prof. Rainer was sure that he had created a modern school of Anatomy at the University of Iasi. In 1919, Professor Rainer was transferred to Bucharest where he furthered his teaching and scientific activity. He is the founder the Institute of Anthropology in Bucharest. He died on the 4th of August 1944, a year after his election as an honorary member of the Romanian Academy. After prof. Rainer`s departure for Bucharest, for the next 9 years, two replacements for the Chair of Anatomy followed: Nicolae Hortolomei (1919-1925) and Gheorghe Zamfirescu (1925-1928).

In 1928 Professor **Grigore T. Popa** became the head of the Anatomy Department. His name was given to the University for Medicine and Pharmacy in Iasi. Grigore T. Popa was an outstanding personality of Romania. His discoveries in the field of physiology (the neuro-endocrine relations or the pituitary portal system) have won him world recognition. In 1963, Professor Harris of the University of Oxford, in an issue dedicated to these findings in the ``Triangle Magazine`` stressed the importance of Popa`s discoveries that became "a remarkable step in the history of world medicine".

Professor Grigore T. Popa was born in

1892 at Şurăneşti, Vaslui. In 1911, he graduated from the National College in Iasi. He received his title of MD in 1920, after graduating from the Faculty of Medicine in Iasi. Between 1914 and 1920 he worked as an honorary assistant at the Descriptive Anatomy Department. After obtaining his PhD he was transferred to the Department of Bucharest, where, after a few months, was promoted to the position of reader. He also became professor at the Anatomy and Embryology Department of the Physical Education Institute in Bucharest (1923-1925). Between 1925 and 1928 he worked in Chicago for the Rockefeller Foundation as Research Fellow. When he returned to Romania, Grigore T. Popa was appointed professor at the Department of Anatomy and Embryology, Faculty of Medicine in Iasi. Gr. T. Popa worked in Iasi until 1941 when he was transferred to Bucharest. In Iasi, he furthered the functional Anatomy school, gathering around him several young people who subsequently became distinguished professors or practitioners (Ion Iancu, Gheorghe Chipail, Nicolae Oblu and others). To his other physiological studies, he added his important research on the anatomy and function of the dura mater, pericardium mechanical structural characteristics, and his research on the vascular pituitary control system. The port microsystem is "a key for endocrine mechanisms" stated Harris. It was originally studied by Grigore T. Popa, then by Grigore T. Popa and Una Fielding of Cambridge. Nowadays the role of this system in neurosecretion is undeniable. Popa's discovery explains the interrelation system, a step towards the elucidation of endocrine physiological, and pathological or adaptive mechanisms like that stress type described by Hans Sellye. Grigore T. Popa`s discovery of the vascular pituitars control system is at the basis of modern endocrinology. A very refined Romanian, aware of the dangers of the period he lived in, Grigore T. Popa together with Mihail Sadoveanu and Mihai Codreanu, outstanding men of letters, founded the journal "Notes from Iaşi" – an important publication for the Romanian culture. In the journal, he contributed to the promotion of progressive social ideas. He also opposed fascism and communism.

In 1932, the head of the Topographic Anatomy Department was Professor **Ion Nubert** (1886-1975). Professor Ion Nubert was born in 1886 in Paşcani. He was a graduate from the National High School in Iasi (1906) and the Faculty of Medicine in Iasi (1914). Professor Nubert worked at the Institute of Anatomy until 1946. The results of his researches were cited in classical treatises. He educated a substantial number of undergraduates. His lectures were always illustrated with a rich iconography. Through his work Professor Nubert linked his name to the history of Anatomy in Iasi, a field in which he worked for more than three decades (beginning in 1915 when he was instructor, lecturer, and then reader - 1931 and full professor, 1932).

After World War II, the Department of Anatomy was led by Professor **Ion Iancu**, are outstanding personality of the medical school of Iasi. Professor I. Iancu was born in 1902 at Liești, Galați. After graduation, he worked as a urologist at "St. Spiridon" Hospital in Iasi after a period of specialization in Paris. Prof. Ion Iancu reorganized the Anatomy Department of the Faculty of Medicine in Iasi. He wrote more than 300 papers on the structure of the rear wall of the trunk, spine, psoas sheath, all his contributions remaining as reference material.

In recognition of his merits, the Institute of Anatomy of the Faculty of Medicine in Iasi was named after him. He was member of numerous Romanian and foreign scientific societies: the Balkan Medical Union, the Romanian Society of Surgery, the French Society of Urology. He furthered the achievements of his predecessors adhering to and promoting the principles of his forerunners, and making no concessions to the then prevailing communist ideology.

Another outstanding personality in the Department of Topographic Anatomy was Prof. Dr. **Nicolae Oblu** (1912-1995), founder of the first Hospital of Neurosurgery in the country (1972) and professors **Gheorghe Adomnicăi** (1923-2016) and **Gheorghe Frasin** (1922-1989) who enriched the studies on the functional anatomy of the abdominal wall.

This article is meant as a tribute to all those who have brought their outstanding contribution to the evolution of Anatomy, as a researcher topic and subject of study, which, regardless of any other opinion, will always remain the"fundamentum medicinae".

This brief presentation of the outstanding personalities of the Iasi school of anatomy aimed at following the main trends of research in a science that is rightly regarded as the key subject in any medical school that offers a sound basis for the medical education of Romanian physicians. Last but not least, the role of the Iasi school of anatomy in the development of the Bucharest school of anatomy and of the Romanian school in general cannot be denied or ignored.

IN MEMORIAM

DOCTOR IULIAN STRATAN - THE PROFESSIONAL, THE MAN, THE FRIEND…

Born in 1938 in a christian family, his father being priest in parish Tibana, where he founded a new church, he was a meritous graduated of the boys' high school from Roman and in 1956 succeeded at the difficult entrance exam (13 candidates for a place) to the Faculty of Medicine in Iasi. In faculty, he belongs to one of the elite group of our series subjecting him to a terrible concurrence which has stimulated him permanent becoming one of the best students. He completed education in 1962 being scored with grade A (10) at the licence exam. According to repartition he opted for a job of trainee doctor at TB Sanatorium from Dobrita ("The Magic Mountain of Romania"), where he was affected to the surgical department. Having the support of an excellent physician Dr. Nicolae Rusdea, the young doctor was directed to the compartment of anesthesia, situated at the beginning in our country and he was precocious-forming in the new specialty.

Succeeding the first at the contest residency he chosen an appointment in Anesthesia-Intensive Care in the IIIrd Surgical Clinic, directed by renowned Professor Gheorghe Chipail who adopted, guided and formed him in the first years of career. He was also resident of Professor George Litarczek, in one of the first series of the newly established specialty and become successively specialist (1970) and senior physician (1978) and from 1980 to 2007 Head of Anesthesia and Intensive Care Clinic of "Sf. Spiridon" County Clinical Emergency Hospital from Iasi.

Devoted until to the sacrifice to his profession, he was continuously preoccupied by his theoretical and practical training and evolution by a solid documentation and frequent participation at refresher courses and national or international meetings getting in the last part of his career as a leading authority in the domain. Predicting perhaps his future professional consumption, he was married early during the college years, becoming a youthful father, grandfather and even great-grandfather. He has not neglected the family, but his time, energy and intelligence were confiscated by the medical activity.

We worked together for more than two decades, benefiting substantially by his competence and thoroughness solving as a team numerous difficult cases, especially in emergency but also in oncologic and endocrine surgery. We have collaborated directly and honestly without pride or preconceived ideas, but mostly conflicts. He did not flaunt his knowledge, but he argued loudest when justice was (almost always) by his side. He was unequaled in sensing of postoperative complications and predicting unfortunate evolutions.

We had no special relationship during the college, friendliness between us formed and perfected in the period of commune

activity, but also in the years we worked in different hospitals.

We both shared the passion for lecture and later for fine arts and classic music. He owned a vast library and was also a faithful auditor of the Philharmonic concerts in Iasi.

He has surprising wide knowledge in all these fields, where we had long colloquies in which I learned much. We often disagreed but without passion or preciousness. Considered to be a difficult man, he masked his shyness and sensibility by an apparent social misanthropy including in the professional environment of that total detached in private conversations where prove a wise, honest and generous man. He demonstrated all these qualities many years during some less happy events in both of our existence.

Finally, he supported with stoicism but conscient and especially with plenty dignity his prolonged sufferance during the last years, leaving us serene and reconciled.

Farewell Iulian….

Mihai Radu Diaconescu, M.D., Ph.D.
Professor of Surgery

EDITORIAL

MUCOSAL HEALING IN ULCERATIVE COLITIS – THE FOUNTAIN OF YOUTH?

Ulcerative colitis (UC) and Crohn's disease (CD) are two distinct pathologies commonly described as inflammatory bowel disease (IBD). UC is a chronic condition with frequent episodes of acute exacerbations and remissions. Its etiology and pathogenesis are still poorly characterized, although an aberrant immune response in individuals with a genetic predisposition is recognized (1).

Advances in the diagnosis and treatment of IBD have led to new perspectives on potential therapeutic targets. Recently, the therapeutic objectives have become more ambitious, going beyond clinical and biological remission, and aiming for mucosal healing, deep remission and even histological remission (2). In this way, clinicians aim for the modification of the natural history of the disease and an improvement in the quality of life.

Mucosal healing (MH) is not a new concept. A number of chronic pathologies, such as chronic duodenal ulcers, have MH as their therapeutic endpoint. Relatively recently Korelitz (3) used for the first time the term MH in the context of IBD.

The definition of MH is not universally accepted. In UC this can be either complete or partial (4):

- *Complete MH* involves the absence of friability, ulcerations and erosions in the rectum or colon (Mayo score 0).
- *Partial MH* involves an improvement in endoscopic appearance and the absence of ulcerations with a Mayo score of 1.

These definitions are however imperfect as they rely to a great extent on the endoscopist's experience and the methods used to improve endoscopic visibility (chromoendoscopy, high contrast imaging which amplifies mucosal details, etc.). Furthermore, there is no consensus regarding the optimal time interval from the commencement of therapy to the assessment of MH (8, 12 or 24 weeks), as well as the interval at which follow-up assessment takes place (5).

MH (the abscence of erosions, ulcerations and friability) is a separate concept from „*deep remision*", which is defined as the abscence of clinical, biological and imaging evidence of inflammation (6). *Histological remission* does not have a standardised definition; histological changes in remision include architectural changes of the crypts and a residual inflammatory infiltrates – a key diagnostic aspect being the abscence of neutrophil infiltration (6). A frequently asked question is whether MH can exist without a normal microbiota. Nevertheless, the answer to this requires further investigation and research.

In UC, MH is determined by colonoscopic means. The most frequently used endoscopic score is the Mayo score (score 0 = MH / inactive disease; score 1 = the presence of slight erosions or friability) and UCEIS (Ulcerative Colitis Endoscopic Activity Index or the Travis score). The latter has the advantage of a more detailed

assessment of the severity of endoscopic lesions, with more reproducible results (5). Although invasive, endoscopic assessment is relatively cheap and remains the principal method of evaluating and stratifying the activity of the disease, monitoring its evolution and assessing treatment response.

An alternative non-invasive method of assessing MH is the measurement of fecal calprotectin. This correlates not only with the extent of UC (higher values in pancolitis and left-sided colitis compared to proctitis) but also with the activity of the disease. Thus, calprotectin values under 50 μg/g suggest "deep remission"; an average value of 477 μg/g correlates with an acute exacerbation whilst two levels above 300 μg/g predict a future episode of acute flare (6). Many studies have demonstrated the role of calprotectin as a prognostic factor for MH (7,8). Roseth et al (7) demonstrated that a normalization in calprotectin levels correlates with endoscopic healing. Rikanek et al (8) demonstrated that the level of fecal calprotectin correlates not only with endoscopic, but also with histological healing.

The concept of MH as an ideal and final therapeutic target is extremely controversial. MH varies depending to the medical therapy used: infliximab 42-62%, adalimumab 25-47%, golimumab 42-45% and vedolizumab 52-56% (9). In some ways, MH has proven its benefits: a rise in quality of life, sustained clinical remission, a reduction in the use of steroids and immunosupressants, length of hospital stay, colectomy rates and risk of colorectal cancer down to similar rate to that in the general population (4,10). These would justify the adjustment in medical therapy to reach MH.

In contrast, an escalation in treatment exposes patients to side effects. According to the most comprehensive analysis published in 2016 (11), there is an increased risk (19%) for infections (not necessarily severe as patients are under surveillance) as well as a two-fold rise in the rate of opportunistic infections. This meta-analysis did not identify a rise in the risk of malignancy (possibly due to a short follow-up period) and did not identify significant differences between the different types of biological therapies concerning side-effects.

An additional controversial matter is whether the attainment of MH allows the cessation of medical therapy. The risk of recurrence at 1 year is 58% for patients in clinical remission, 36% in those with incomplete MH and 28% in those with complete MH (6). It is known that the episodic use of anti-TNF agents ('holiday drug administration') is associated with a raised risk of immunization, hypersensitivity and loss of effect (12). In contrast, the possibility of attaining an 'indefinite remission', the risk of side-effects and raised costs are justifications for cessation of biologic therapy in patients with MH. Recent studies (13) suggest that the treatment of a new flare episode with the same anti-TNF alpha agent that had been interrupted is efficient, leading to remission in 80-92% of cases. A possible explanation for this high remission rate could be the use of an anti-TNF agent in a selected group of patients that are responders to anti-TNF.

In conclusion, MH represents a therapeutic target with multiple benefits in clinical practice. There is insufficient data to make firm recommendations, with the decisions to increase (in order to achieve MH) or interrupt therapy (after complete MH) being case

specific, dependent on a risk-benefit analysis and taking in account the patient's choices. Complete MH does not however signify complete healing of the patient, mandating ongoing careful monitoring efforts. Despite all the recent advances, clinicians must have the wisdom to understand that they continue to treat IBD, not heal it.

EDITORIAL

THE MEDICAL-SURGICAL JOURNAL IS 120 "VOLUMES" OLD

In his celebrated work, The Structure of Scientific Revolution (1962), Samuel Thomas Kuhn challenged the idea of cumulative unidirectional scientific progress. His theory of paradigms as sets of related concepts which compete for acceptance in times of rapid scientific change or revolution might be significant even for someone interested in understanding the development of Romanian science. The case of the Medical-Surgical Journal is a resourceful field in this respect.

In 1830, on 11 January, dr. Michael Zotta and dr. Iacob Czihac started *The Reading Circle (Cercul de Cetire)* with its 21 members. Three years later the Circle turned into *Societatea de Medici și Naturaliști (The Iasi Society of Physicians and Naturalists) (henceforth SMN*), the first modern scientific society in Eastern Europe, similar to institutions of the same kind in Western Europe. From the today perspective this society (SMN) may be considered the oldest scientific institution in Eastern Europe that introduced the scientific spirit of the age (1).

SMN was compared to a diamond in the crown of Moldavia that was later set into the great crown of modern Romania as its unionist members, assembled at its headquarters, in the very heart of the city of Iași, nominated and then elected Al. I. Cuza, prince of the united modern Romania, on Jannuary 5, 1859. The nomination and election of Al. I. Cuza in Wallachia too, on Jannuary 24, 1859 was a confirmation of the right decision taken by the Moldavian unionists, members of SMN: *"Nothing worthier of respect, admiration and imitation than the successful aspiration to our country's prosperity of those great men and scholars who planted the first tree to start an oasis of science in the wasteland of thought and culture that overwhelmed our beautiful Moldavia then, because of the difficult times it passed through. The foundation of SMN in Iasi was the first spark that illuminated the dark horizon of the Romanians' future prospects, who at the time enjoyed more freedom. From the deep and fertile furrow made by this scientific society, the Museum of Natural History, the Academy of Prince Michael Sturdza and finally the University of Iaşi were born "*(C. I. Istrati 1887) (cit 2).

Obviously a scientific society cannot long exist without a periodical that should aim at spreading the results of its members' research. Consequently, on the 1st of January 1844, C. Vârnav published an Adviser Journal for a Healthy and Economical life, a Periodical for the Romanian People, (Povățuitorul sănătății și economiei, foaie periodică pentru poporul românesc), similar to Franklin's almanac, that later on became the leaflet of the Society of Physicians and Naturalists from the Principality of Moldavia. As the scientific activity enhanced, in 1887 the leaflet was turned into the Bulletin of Society of the Physicians and Naturalists (Buletinul Societății de Medici și Naturaliști) (2). From 1924 on, the title of the periodical became The Medical-Surgical Journal (Revista Medico–Chirurgicală) (henceforth MSJ). The SMN members founded the Faculty of Medicine

(1879), *"which though recently initiated and in the process of development pioneered several research projects"* (2), making possible the emergence of one of the first genuine scientific publication in Romanian. The MSJ journal and the Faculty of Medicine have always lived in a happy symbiosis, symbolized by the image on the seal of SMN that is still in use: a snake and a cup, symbols of healing.

On January 1st 2016, 129 years since the publication of the first issue of MSJ was celebrated. In spite of this, because of the difficulties encountered during the two world wars, the 100th volume was issued only in 1996. It follows the MSJ appeared only 120 years out of 129. The 120 volumes are carefully preserved in the library of SMN, one of the oldest in Eastern Europe. Flipping through the 120 volumes of the Journal (MSJ) one lives a deep emotion that makes him/her aware that you are not only in front of a historical treasure in which you may identify the essential hallmarks in the development of medicine in Moldavia, via the research papers published here, but also an encounter with the outstanding personalities of the Iasi School of Medicine and of the other national medical schools (3).

Three main periods may be identified in the history of the MSJ: the first period, 1887-1923; the second period between 1924-1948; and the third: 1956 till our time which is also the most prolific period if we take into account the number of papers published in the issues of MSJ. A glance at the contents of the 120 volumes of MSJ allows us to assess that all the chief editors did their best to offer the MSJ readers highly original scientific papers. Moreover, "*this journal had from the inception a European level, and its publication was possible owing to the high scientific and cultural level reached by a multicultural Iasi* "(4).

The first issue of 1887 of MSJ was published in Romanian and French, the two versions being placed side by side on the same page. The editors stated in their editorial that *"As science enjoys the attribute of universality, those who work in this field should meet the requirements of this characteristic. It follows that MSJ could have been far from reaching its final goal if the papers published in MSJ had not been presented to the international readers in a form that could allow them to quickly inform themselves about the content of the papers they were interested in and easily guiding them to a correct assessment of their scientific value"* (3). In a period when the Romanian medical discourse was still in a process of formation and consolidation, MSJ played a major role in the development of the language of medicine in particular and the scientific discourse in Romanian in general. In this respect it is worth mentioning that the philologists SMN's may find the Journal a rich source for their scientific research. So far, some researchers wrote about the role of phonetic adaptability of neologisms from French in the formation of the language of medicine (4).

The first issue of SMN's journal, MSJ was published by an Editorial Board, that included dr. Aristide Peride, professor dr. Grigore Cobălcescu, Prof. Gustav Otremba, dr. Eugen Rizu, dr. Constantin Bottez, dr. Samoil Konya (although the first supporters of the idea were Anastasie Fătu and Ion Ciurea), who identified themselves with the SMN's board of directors. From 1888 on, the journal was published with an accompanying note*: "published under the direc-*

tion of dr. George Bogdan", the first outstanding personality from among the members of the editorial board. In this form the journal (MSJ) was published regularly until 1900. At the time, the journal (MSJ) was well known among European scholars as prof. George Bogdan took great care to provide*”a variety of printed materials that could interest both physicians and biologists”*. It is amazing for us, even today, that a society (SMN) made up of 49 ordinary members, in 1896, managed to support the publication of an important European journal. The proof of its popularity was the fact that 92 foreign scientific journals favoured exchanges with this outstanding scientific journal.

Between 1912 and 1916 MSJ was published exclusively in French under the title *”Bulletin et Memoires de la Societe des Medecins et Naturalistes de Iassy”.* The issues published in French strictly adhered to the high academic standards that had always characterized the Journal (MSJ). The contents of the issues published in the first period included medical studies, case studies, medical morbidity studies, reviews of the specialized journals of Europe, book and textbook reviews etc. (5).

At the beginning of the 20th century, until Romania became one of the belligerent countries, the Journal (MSJ) was coordinated by an editorial team that gradually became more and more dynamic. The editorial board included famous personalities of Iași school of Medicine. Among them E. Juvara, G. Socor, P. Bothezat, A. N. Brăescu, L. Russ Junior, C. Demetriade, P. Anghel, C .Botez, L. Buteanu, E. Pușcariu, I. Tănăsescu, S. Konya, C. Bacaloglu, P. Zosin, A. Tzaicu.

Other changes may be easily noticed during that period. If in the first years of MSJ’s existence, the number of articles signed by naturalists surpassed the number of medical studies, at the beginning of the 20th century the number of articles on medicine increased. (4).

Unfortunately, in the period 1916 - 1923 the publication of the journal (MSJ) was discontinued obviously because of the difficulties the editors encountered during the Great War when Iasi became the capital of unoccupied Romania. From 1924 on the bulletin was published with the title ”*The Medical- Surgical Journal”* (MSJ) , with a subtitle of *"transition"* which reminded readers of the old title *Bulletin of the Society of Physicians and Naturalists.* This time the journal became mainly medical in its content and aimed at concentrating Iasi medical creativity and spreading the new gains in the field at the international level.

In 1925, the MSJ was published in 6 issues. The editorial board consisted of outstanding members of Iasi school of medicine: C. Bacaloglu, N. Hortolomei, I. Mironescu, V. Răşcanu, A. Slătineanu, Elena Pușcariu, C. Ionescu Mihăești, M. Ciucă, I . Tanasescu, I. Enescu; the secretary of the editorial board was I. Alexa. During that period, the structure of the Journal (MSJ) was improved. The articles were grouped into: original papers, book reviews, review of reviews, aspects from the scientific life of SMN, in particular, and medical life, in general. Nobody can state that between the two world wars there were no other possibilities for publication, mainly abroad, but obviously the members of the teaching staff of the Faculty of Medicine preferred to publish the results of their research in MSJ aiming at the same time to achieve everybody’s dream: to offer the medical communities a journal that could rival other European publications

from the same field. No wonder that news about the latest discoveries in physics and chemistry that could have an impact on the medical science was always present (4).

During MSJ's second period, the most productive years were 1926-1931, as in other spheres of life, each volume had more than 600 pages. The topics of the papers published during that period reflected in fact the interests of the epoch mirrored in the main research projects. After 1940 celebrated professors from the Iasi School of Medicine were included in the editorial board. Unfortunately that glorious period in the history of SMN and MSJ came soon to an end. Among the new names of the editorial board it is worth mentioning the names of: L. Ballif, I. Nicolau, O. Franche, Gh. Tudoranu, J. Nițulescu, A. Moruzzi, Gh. Nastase, Gh Plăcinţeanu, N. Balan, L. Wasserman.

Although the Journal (MSJ) encountered countless difficulties during the Second World War, the enthusiastic editors succeeded in publishing the journal regularly until 1943: *"The printed materials for the last 1943 issues of MSJ were destroyed before their publication. The building of SMN was badly damaged by 11 bombs, 4 of which fully hit the building, and almost demolished it. It was no surprise to see that the medical collections gathered with so much hard work and displayed with so much care were lost for ever. In spite of this, after so much material loss, to say nothing of the spiritual and social waste, our predecessors found enough energy to gather all forces so that the publication of the MSJ could continue. Everybody dreamed of calmer and better times* ... "(vol. 57, 1946). (cit 4). But the hope was futile. In 1949 MSJ ceased to be published as the new communist authorities were obsessed of the idea of having an absolute control of everything that was published. All publications were supposed to be censured and distributed from Bucharest.

The policy of absolute control of all publications that could publish subversive material lasted until 1956 when the 60th volume was published. The editorial published in that issue was signed on behalf of the editorial board by Vasile Rășcanu, member of the Romanian Academy, who did his best to demonstrate to the communist authorities the importance of resuming the publication on of this outstanding medical journal. The title of the editorial was telling: *The Historical and Scientific Significance of MSJ of Iasi* (pp. 1-4) (5).

The publication of the 60th volume of RMC marked the third period, also a productive one. The members of the editorial board included V. Rășcanu, member of the Romanian Academy (editor in charge), professors Ș. Brăteanu, Vl. Butureanu (deputy editor), T. Economu, reader Dr. I. Kleinstein, reader G. Popovici and E. Ungureanu (secretaries of the editorial board.). Many consider that that was the gold age of RMC which culminated in the appointment professor Prof. Gregory Teodorovici as editorial secretary. Until 1966, all the published issues numbered almost 20 million pages. RMC had at the time 2,000 subscribers (3). Besides V. Rășcanu, member of the Romanian Academy, editor-in-chief between 1956– 1974 to whom we owe our gratitude for the persuasive plea in favour of resuming the publication of RMC, two other personalities are worth mentioning: Gregory Teodorovici (1975 – 1992) and Valeriu Rusu (1995 – 2014) who dedicated much of their lifetime to this journal. They employed all their competence and editorial talent to the prosperity

of MSJ. During that period the RMC was indexed in PUB MED and INDEX MEDICUS.

The scientific level of MSJ which celebrated the publication of its 120th volume was highly appreciated by similar journals and societies, among them the Society of Hygiene of the United Nations that ranked MSJ among the important medical publications, its history mirroring the ups and downs of Romanian medicine (6). In 2008, 1160 pages were published in the four issues. More than 1,000 medical specialists subscribed to this outstanding journal. Since 2012, MSJ has been published only in English. At the same time MSJ is currently being monitored to be included in the new database ISI Thompson , (03, 03, 201).

The late editor-in-chief who was extremely devoted to MSJ was Valeriu Rusu. He was aware of the steps that had to be taken in order to overcome to difficulties that MSJ encountered during the long period of transition that followed the 1989 events which more or less destroyed consciously or unconsciously some of the good achievements of the past: *"first of all we need a coherent editorial board that fully accepts the responsibility and obligations encountered by this position. Such o board of editors should be motivated to get rid of the sometimes exacerbated individualism if they were ready to offer their time and intelligence to this medical journal of Iasi that fully deserved that sacrifice. We should be aware that MSJ can "coexist" with similar publication that had been published under more favourable conditions if everybody accepts the idea that the journal (MSJ) means, after all, an important tradition that has to be defended and continued. This awareness should be developed in the collaborators who should be conscious of the exigencies of a journal indexed Index Medicus, PUB MED i.e. they should realize that their scientific contribution is signalled in the largest database in the world. Consequently, the editor should exercise a more rigorous assessment of all contributions, mainly by accepting the idea of the importance of external reviewers who could enhance the responsibility of the authors. Obviously the form of presentation is extremely important. The authors should strictly observe the presentation requirements of the journal"*(4).

A summary of the important contributions of MSJ is worth attempting. MSJ: encouraged the use of the Romanian language in science; contributed to the development of the medical discourse in Romanian; played a major role in foundation of the first institutions of high learning: Prince Michael s Academy (1835), the University of Iasi (1860), the Faculty of Medicine (1879); founded the first medical library as a result of exchanges with more than 150 periodical journals and of the book donations from the members of SMN; promoted scientific research, education and the spread of medical knowledge; made known the medical school of Iasi all over of the world; took part in the main national events always on the side of the progressive forces (e.g. the Union); mirrored the world scientific trends of the age; contributed to the promotion of the academic staff of the University of Medicine and Pharmacy of Iasi (a truth almost forgotten today by many members of the medical school); brought together scientists of various origins, a proof of the importance of positive multiculturalism; published outstanding original papers signed by many leading scientists from all over the world; promoted the movement towards education for

health, undergraduates' instruction and teaching staff's training.

This celebrated scientific society (SMN) and its journal (MSJ) passed through two world wars, the communist dictatorship, a long period of painful transition after 1989. In spite of all these difficulties they survived. It is once again a proof that *"the great works of humanity are achieved by people who succeed in overcoming the infirmities of an age."* (G. Scripcaru) (6). From the very beginning, MSJ had a distinct European personality, that aimed at strengthening and pursuing those values that embodied the scientific spirit of the age. This year we celebrate SMN's 186 years of existence and its long-life journal (MSJ).

This brief presentation of the key events in the development of Romanian medicine is also an encounter with the great personalities that gave life to the two institutions. All this has been done with a deep reverence given to the words on the 183 years old seal of SMN that is still made use of: *Semper Altius.*

HUMAN PAPILLOMAVIRUS AND SQUAMOUS CELL CARCINOMA OF THE HEAD AND NECK

Whole scientific world is talking about Human Papillomavirus (HPV) and his role in the oncogenesis, but after all who is this virus? .HPV is small (50-55 nm in diameter), non-enveloped, double-stranded DNA virus which primarily infect epithelial cells of the skin and mucous membranes. They are associated with a variety of clinical manifestations that range from benign lesions to cancer. The spectrum of diseases associated with HPV infections has accompanied humans throughout evolution. Papillomatous and verrucous skin and genital lesions have been described since ancient Greece and Rome. But until early twentieth century, research of HPV has not been started yet. Indication that now recognized HPV-associated diseases could be related to sexual transmitted infection dates from 1842 year when Italian physician Rigoni-Stern noted a high frequency of cervical cancer in married women, widows and prostitutes, but their rare occurrence in virgins and nuns. After visualization of papillomavirus particles in human warts by electron microscopy and characterization of HPV genome interest for HPV started to arise. Zur Hausen postulated and analyzed a possible role of HPV in cervical cancer development. The first HPV types (HPV16 and 18) were isolated from cancer biopsies of the cervix and were cloned in 1983 and 1984, respectively. Further epidemiological studies have confirmed that cervical infection by high-risk (HR) HPV types is the main risk factor for cervical cancer development. The role of HPV in the pathogenesis of squamous cell carcinoma of head and neck (SSCHNs) was first described in 1983, when histopathological features consistent with HPV infection were identified in oral cancers. Two years later, viral DNA from high-risk HPV-16 was detected in an oral carcinoma by Southern blot hybridization. By the early 1990s, discoveries of HPV in association with oropharyngeal carcinomas became consistent. In 2008, the Nobel Prize for Medicine was awarded to Dr. Zur Hausen for the discovery of the infection etiology of cervical cancer.

Currently, we have more molecular evidence that indicates a relationship between high-risk HPV and the pathogenesis of oropharyngeal cancers. Expression of HPV *e6/e7* oncogenes are the current criterion standard for determining a causal role of oncogenic HPV in human tumors. The *E6* and *E7*genes produce oncoproteins and are responsible for the degradation of p53 ,which are important events that lead to dysregulation of the cell cycle and thereby immortalization of the cells. The silencing of p16 by promoter methylation is commonly observed in SCCHNs. In contrast, HPV is readily detected in HPV-positive tumors and is highly correlated with p16 expression, which is most likely the result of transcriptionally active HPV infection. Therefore, there is a relationship between HPV the expression of p53 and p16 in oropharyngeal cancer and clinic-pathological variables. The diagnosis of HPV positivity should enter as a routine test for these patients. The most clinically

useful test, *in situ* hybridization, is available in only few centers, so that is unfortunate, even if p16 immunohistochemistry may serve as a reasonable surrogate and PCR – molecular detection of HPV DNA. It is widely accepted that the most common risk factors for SCCHNs are tobacco use, heavy alcohol consumption, betel quid chewing, and high-risk HPV infection. High-risk HPVs are currently well accepted as causative agents for most cervical cancers and have recently been associated with a subset of head and neck cancers. Oropharyngeal cancer has emerged as another mucosal cancer that is associated with HPV infection. HPV DNA is present in 20% of all SSCHNs and in nearly 60% of tonsillar cancers. Traditionally, most cases of oropharyngeal cancer were associated with chronic tobacco and alcohol use. This exposure resulted in the mutation loss of the genes p16 and p5. Decreased use of tobacco coupled with an increase in the HPV + of oropharyngeal cancer has shifted the majority of these types of cancers to now occur more commonly in non-smokers. An "epidemic " of HPV oropharyngeal related cancer has been identified and attributed to HPV + disease in many cases thought to result from oral genital contact.

Patients with HPV + cancer are less likely to smoke tobacco and less likely to use alcohol heavily, are heaving a better dentition, are heaving a higher incidence of oral sex practice, younger and higher socioeconomic status. Having in mind this two types of oropharyngeal cancers, HPV+ and HPV – and their molecular changes that concern the expression of p16 and p53 genes , we can conclude that patients with HPV + cancer have an higher expression of p16 and a lower expression of p53, responded well to treatment and showed good prognoses. The T stage in TNM (tumour, node, and metastasis) stage does not differ from HPV status, HPV + tumors are more likely than HPV –tumors to have a lower T stage, whereas advanced T stage is a significant risk factor for recurrence and death, independently of HPV status. Patients with p16 + oropharyngeal tumors are less likely to have persistent viable tumor in neck lymph nodes after (chemo) radiotherapy and hypothesized that a post treatment planned neck dissection may perhaps be avoided. Several authors indicate that the impact of HPV status must be evaluated in prospective clinical trials and included as a stratification factor to avoid potential confusion .The current American Joint Cancer Committee staging system for oropharyngeal cancer needs to be modified in order to be better reflect different prognoses for patients with HPV+ or HPV – tumors and those with vegetating or infiltrating tumors.

HPV-related SCCHN represents a new entity well- defined with a well- known characteristic that includes young age, good performance status, male gender, nonsmoking and nondrinking status, basaloid tumor histology and high-risk sexual behavior. The practicing oncologist needs to be aware of these new findings, and HPV testing with PCR or FISH, should be perform routinely. For now, results will have significant prognostic though not therapeutic implications. Still, changes come rapidly in this field and we expect that different treatment will be available to these patients in the near future.

In conclusion, what do we wish for these patients? We wish a modified TNM stage for HPV + tumors? We wish a genic and antiviral HPV specific – therapy? We wish a fuller utilization of HPV vaccine

and public education measures?

Personally, I am having great expectations within the scientific progress in this field so we could have some day the responses to those questions above, all for an early diagnosis, a specific treatment and a long term prognosis for the HPV positive related SCCHN s. Multidisciplinary dedicated clinical practice with integrated research, I consider to be an important aim.

THE TRIBES AND TRIBULATIONS OF LARYNGOPHARYNGEAL REFLUX: A REVIEW OF RECENT STUDIES WITH IMPLICATIONS FOR INTERDISCIPLINARY COLLABORATIONS BETWEEN OTOLARYNGOLOGY AND GASTROENTEROLOGY (Abstract) Laryngopharyngeal reflux has been recognized since 2006 (Montreal Consensus) as an extradigestive manifestation of gastroesophageal reflux disease. However, despite numerous research studies, the relationship between these two pathologies is yet to be fully understood. The aim of this paper is to review the literature of the last five years available via the PubMed database, looking at the controversies about the prevalence, pathophysiology and diagnosis of laryngopharyngeal reflux. **Keywords:** LARYNGOPHARYNGEAL REFLUX, GATROESOPHAGEAL REFLUX DISEASE.

Laryngopharyngeal reflux disease (LPR), also known as supraesophageal reflux disease, atypical gastroesophageal reflux disease (GERD) or reflux laryngitis, represents an extradigestive manifestation of GERD due to the reflux of gastric content through the esophageal/ pharyngeal/laryngeal axis (1). Although GERD and LPR are considered to be part of a spectrum within the same disease, they are different clinical entities produced through different pathophysiological mechanisms. Reflux laryngitis is still a challenge for both gastroenterologists and otolaryngologists. Even though the cause-effect relationship assertion between GERD and LPR has been strengthened by more recent evidence, the causality, diagnosis and treatment remain controversial. Since Koufman coined the term "LPR" in the 90's, reflux laryngitis has been most frequently recognized by Ear, Neck and Throat (ENT) surgeons and gastroenterologists, but also by other medical specialists (pneumologists, cardiologists etc), even to the point of being over-diagnosed (2). For example, in the USA, during a period of 11 years, the number of ENT consultations for clinical conditions related to GERD in-

creased by over 300% and the prescription of proton pump inhibitor (PPI) also multiplied about 14 times (2).

Epidemiology and pathophysiology. The mechanisms involved in the pathophysiology of LPR may be related to the direct injury of the esophageal and pharyngolaryngeal mucosa by the gastro-duodenal content, with or without micro-aspiration in the respiratory airways. The larynx is an organ about a 100 times more sensitive than the esophagus and is at high risk of injury because of its immediate proximity to the digestive system (3). Thus, only a small amount of gastric content is sufficient to cause lesions of the larynx. The second mechanism that is incriminated in the pathophysiology of LPR is the tracheal-bronchial reflex mediated by the vagal nerve, produced by the acidification of the distal esophagus, and which determines cough, throat clearing and laryngospasm (3). The vocal folds are covered by stratified squamous epithelium which creates a barrier against external and internal factors, including reflux. Erickson and Sivasankar conducted a study using transepithelial electrical resistance (TER) for assessing the permeability of the epithelium of the vocal folds. They found that the exposure of vocal folds to refluxate determines the decrease of TER, making them more susceptible to injury (4). It has also been demonstrated that carbonic anhydrase type III plays a protective role of the epithelium of the larynx, as it regulates cellular pH when the larynx comes in contact with acid by producing bicarbonate (5). Ford (1) showed that this enzyme was absent in 64% of patients with LPR. The peptic injury was also associated with depletion of other key protective proteins such as E-cadherin and the stress proteins (e.g. Sep 70) (5).

The exact actual prevalence of reflux laryngitis is hard to determine because of the different clinical presentations of LPR, added to the lack of consensus regarding LPR diagnosis and treatment. It is estimated that 4-10% of patients who seek otorhinolaryngologic services suffer from reflux disease. At the same time, LPR was identified in more than 50% of dysphonic patients (6). In last decades, the prevalence of GERD and LPR has increased dramatically. Using a statistical model in an analysis of 17 studies, El-Serag (7) showed that the average increase rate of reflux disease since 1976 has been 4% per year (P <0.0001). An interview-based study on 656 subjects revealed unexpectedly high percentages of people living with GERD - 40% (22% with typical GERD and 18% with LPR) across the USA. In addition, many patients were young – 21-30 years old (37%). Regarding causality, food additives were now considered to play a significant role, apart from the historically acknowledged obesity (8).

Clinical manifestations of LPR. Despite the association between GERD and LPR, the diagnosis of reflux laryngitis remains a difficult task. First, a complete and accurate anamnesis is needed in order to diagnose this pathology. According to the study published by Koufman two decades ago we should discriminate between GERD and LPR as distinct clinical entities (3). The symptoms of LPR are diverse and many physicians may not link these symptoms toLPR. The most common manifestations of LPR are dysphonia/ hoarseness, throat clearing or pain, chronic cough and globus (9, 10). But it is known that these symptoms are nonspecific to LPR and can also be found in other diseases such as postnasal drip syndrome, exposure to dif-

ferent allergens or environmental irritants like smoke or vocal abuse. Because symptoms are not exclusive to LPR, the clinicians should rely on a combination of manifestations and diagnostic tools such as laryngoscopy exam, impedance-pH monitoring and empiric trial of proton pump inhibitors (PPI) to establish an accurate diagnosis. It is important to emphasize that patients with LPR do not usually present typical GERD symptoms (heartburn and regurgitation), which can make proper diagnosis more difficult (1).

Diagnostic methods. ***Laryngoscopy.*** The diagnosis of reflux laryngitis is usually performed by ENT surgeons. Transnasal fiberoptic laryngoscopy is the first-line method to be used by otolaryngologists to diagnose LPR. Laryngoscopic exams are essential for excluding neoplasms, but their role in detecting GERD-associated laryngitis remains uncertain. There is a low inter-rater reliability among ENT surgeons evaluating the same laryngeal signs, and that is the reason why LPR diagnosis may be subjective and inaccurate. The specificity of the laryngeal signs of LPR is still debated in the literature. The most frequent laryngoscopic lesions that have been found to be related to GERD were edema and erythema, particularly in the posterior region (9). These were the main findings used by different researchers for the diagnosis of LPR, while ulcers and ventricular obliteration, nodules, polyps and leukoplakia were reported to be less useful. In another study, pseudosulcus was found to have 70% sensitivity and 77% specificity in patients with LPR (11). In 2007, Vavricka et al. (12) evaluated the prevalence of specific laryngeal lesions thought to be GERD-related, both in patients with documented reflux and normal subjects. They found that the prevalence of laryngeal lesions was the same in both groups. Only posterior pharyngeal wall findings showed a statistically significant higher prevalence in GERD patients as compared to the control group. Furthermore, the study of Hicks et al. revealed that the most signs seen in patients suspected of LPR were also found in healthy, asymptomatic subjects (13). To improve the diagnostic accuracy, Belafsky et al. developed the Reflux Finding Score (RFS) based on the presence and severity of the lesions found in laryngoscopy (14). This nine-item scoring system including the most common laryngoscopic lesions has great reproducibility and is useful to evaluate the effectiveness of therapy in patients with LPR. Thus, the laryngeal lesions have low specificity for LPR and that is the reason why patients initially diagnosed with reflux laryngitis do not respond to antireflux treatment. However, Park et al. showed a high specificity of the laryngeal findings for LPR (91%) (15). Rafii et al. demonstrated that LPR may be over diagnosed, all the 21 patients included in the study, had already been diagnosed with laryngopharyngeal reflux disease (16). In fact, all suffered from other laryngeal pathologies, different from LPR, as the cause for their chief complaint of dysphonia. The most common findings were vocal fold paresis (29%) and muscle tension dysphonia (14%). Therefore, the recommendation is for a diagnosis of reflux-induced laryngitis to not be made based on laryngoscopy findings alone.

Upper digestive endoscopy (UDE). UDE has excellent specificity for the diagnosis of GERD in the presence of an erosive esophagitis, but only one third of patients with GERD symptoms and even fewer after treatment with PPIs have ero-

sive esophagitis (17). However, erosive esophagitis could be generate also by other pathologies (e.g. Candida esophagitis, varices) that were found in 25% of LPR patients (18). It is important to notice that, although upper endoscopy is necessary to rule out esophageal cancer, it is not a specific diagnostic test for LPR. Indeed, it has been reported that up to 80% of LPR patients have normal UDE. Red flags that necessitate early endoscopy include dysphagia, bleeding, chest pain, weight loss or dyspnea.

Ambulatory pH monitoring/ impedance-pH monitoring. Ambulatory reflux monitoring is a diagnosis method which can demonstrate the presence of GERD by documenting an abnormal esophageal acid exposure. A 24-hour-double-probe (simultaneous pharyngeal and esophageal) pH monitoring has been the gold-standard for LPR diagnostic in last twenty-five years (19).

The sensitivity and specificity of ambulatory pH monitoring as a means for diagnosing GERD in patients with extraesophageal reflux symptoms have been challenged (6). Koufman showed a sensitivity of 24-h dual-probe pH monitoring ranging from 50% to 80% (8). In the presence of esophagitis, the sensitivity and specificity of this method is higher (up to 100%), but in patient without esophagitis, the sensitivity is dropped to about 70% (20). Also, it has been determined that pH monitoring cannot predict the severity of patient's reflux laryngitis symptoms or signs and only the heartburn correlates with LPR. There is great variability in the reported prevalence of abnormal pH monitoring in patients with laryngitis. A pathological reflux detected during a pH measurement does not confirm GERD as the cause of the laryngitis as well as a negative pH monitoring test can direct the diagnostic toward non-GERD etiologies. However, ambulatory reflux monitoring may be used to determine whether the patients' symptoms are related to reflux or not. The temporal association between reflux episodes and ENT symptoms may be evaluated by two methods: the symptom index (SI) and the symptom association probability (SAP) (21). For these methods to yield results, the patient has to keep a log and use a detection device accurately and timely.

The availability of multichannel intraluminal impedance and pH monitoring (MII-pH) seems to perform better in the diagnosis and management of extraesophageal manifestations of GERD than pH-testing alone (22). It is currently emerging as the new "gold standard" for clarifying differences in PPI refractory symptoms. Esophageal pH-impedance monitoring is a method that detects both the antegrade and retrograde movements of the refluxate and evaluates the physical (liquid, gaseous or mixed) and chemical (acid or non-acid) nature of the refluxate. According to the American College Guideline published in 2013, impedance-pH is used to establish the diagnosis of GERD when: the diagnosis is uncertain, or before consideration of endoscopic or surgical therapy in patients without esophagitis, or in the evaluation of patients refractory to PPI therapy.

A very recent study (23) comparing MII-pH and Bravo® capsule in patients with LPR symptoms found high prevalence of discordant esophageal pH results, most commonly a negative MII-pH testing, but positive Bravo testing. The researchers considered that the Bravo test results were more likely to be true, as the patients included in the study presented characteristics consistent with GERD (heartburn, defective LES, hia-

tal hernia). They concluded that MII-pH catheter study may be inadequate to diagnose GERD in the patients with both typical and atypical symptoms.

A new technology able to detect aerosols of acid and gaseous clouds of acid tends to be more used in patients with LPR. The Dx-pH measurement system® (Respiratory Technology Corp., San Diego, CA) is a highly sensitive and minimally invasive device for the detection of acid reflux in the posterior oropharynx. It uses a nasopharyngeal catheter with the pH probe placed in the oropharynx instead of hypopharynx and it measures the pH in either liquid or aerosol droplets (24). The advantages of this method are that it does not require manometry or endoscopy and the catheter is better tolerated as it does not traverse the upper esophageal sphincter. However, it is limited because it cannot confirm if a reflux event originates in the stomach, since it does not entail simultaneously probing the esophagus.

Empirical PPI treatment. The therapeutic test with PPIs is considered by many clinicians as a reasonable approach to the diagnosis of LPR, in which a favorable response is defined as diagnostic confirmation (18). Most published researchers consider a favorable response when there is a resolution of LPR symptoms after 3 months of double dose PPI trial. But the role of PPI trial is still controversial. A meta-analysis of randomized studies has demonstrated no benefit of PPIs vs. placebo in diagnosing GERD-related laryngitis (25). A placebo-controlled study including patients with LPR showed an improvement in 50% of patients when using placebo compared with 53% of patients who received PPIs (26**)** .Due to this seemingly strong placebo effect, patients who have some response to an empiric PPI trial may be incorrectly diagnosed with reflux disease. Nowadays, the current recommendation for the empirical trial is to include patients with concomitant typical symptoms of GERD (1). The advantage of this diagnostic tool is the cost-effectiveness, the ease of use and its sensitivity, but it lacks specificity.

Pepsin testing. The use of the pepsin test to diagnose GERD is justified, because pepsin is produced exclusively by the stomach. The pepsin test (Peptest) is a non-invasive, quick and inexpensive tool for the diagnosis of LPR. It consists of a lateral flow device that uses 2 monoclonal antibodies to human pepsin to detect the presence of pepsin in saliva. Its results can be read very easily in 5-15 minutes. Because of the benefits and ease of application, a positive salivary pepsin test in a patient suspected of having LPR can be a cost effective, accurate and alternative diagnostic method. Yuksel et al. (27) found sensitivity and specificity of 87%, a positive predictive value of 85% and a negative predictive value of 68% for the pepsin test in the diagnosis of LPR. In a very recent cross-sectional study, *in vitro* pepsin detection tests were compared to the 24-hour double probe pH monitoring results for patients with suspected LPR (28). The authors found a sensitivity and specificity of the pepsin detection test of 33% and 100%, respectively. A positive predictive value of 100% was recorded.

Current diagnostic tests for GERD and LPR are suboptimal and do not accurately and reliably measure chronicity of reflux. New methods to diagnose LPR are needed. Recently, a minimally invasive device has been developed to assess esophageal mucosal impedance (MI) as a marker of chronic reflux. Ates et al. conducted a prospective

longitudinal study using a prototype device to investigate MI patterns in patients with GERD and common non-reflux conditions, to assess MI patterns before and after treatment with PPI and to compare the performance of MI and wireless pH tests (29). They discovered that measurements of MI detect GERD with higher levels of specificity and positive predictive values than wireless pH monitoring. They are hopeful that this device may be employed in the future also in patients with LPR.

Another diagnostic method that offers an objective and quantitative alternative is computer-based analysis of laryngeal image color and texture features. The study of Witt et al. suggested that a combination of laryngeal hue and texture features could be used to diagnose LPR (30).

CONCLUSION

Laryngopharyngeal reflux is being diagnosed increasingly frequently in recent years, especially by ENT surgeons and gastroenterologists. It has become one of the most common reasons why patients see otolaryngologists. LPR is considered to be a different clinical entity than GERD as it features different symptoms, clinical manifestations and treatment objectives. The controversy about its pathophysiology and diagnosis continues still, despite the numerous studies that have been published in the last 5-10 years. We consider that upon initial consultation, the ENT specialist should be able to recognize reflux laryngitis signs and symptoms and refer the patient to a gastroenterologist, thus acknowledging the importance of interdisciplinary collaboration in such cases. Given that LPR diagnosis and treatment have not been standardized, we emphasize that further large randomized-controlled trials are needed for more accurate diagnosis.

POINTS OF VIEW

THE METABOLIC SYNDROME: PROS AND CONS

The alarming increase in number of cardio-vascular diseases (CVD) in the 20th century has determined the onset of many epidemiological studies *(using the Framingham pilot-study model)* to identify the determinants, that led to the outlining of risk factors (RF); the prophylactic efforts focused on the changeable factors *(biological and behavioral)*, and the control over them proved to be efficient. Finding that the vascular accident risk increased by the number and quantity of such factors, created the possibility of assessing the global risk in each individual by a general risk score calculator, and the intensity of therapies was such shaped to achieve the therapeutic goals specific to the risk level. Finding that the combination of some major risk factors might have an additive or multiplying effect (1) has encouraged the development of holistic strategies, with arguments grounded on the outcomes of multiple therapeutic studies, according to the concept of evidence-based medicine.

The observance of more frequent combinations of risk factors led to the outline of the metabolic syndrome (MS) or cardiometabolic (initially proposed by Reaven under the name of Syndrome X) concept. MS appears as the result of this conceptual revolution in the management of CVD. The fact that, by adjusting the other major RFs (LDL-cholesterolemia included), the presence of MS would increase the mortality risk of CVD by approx. 3-4 times compared to the absence of MS *(Kuopio Study - posthoc analysis) (2)* enabled this concept to be put into practice. Finding that MS is often associated with a pro-inflammatory *(increasing PCR)* (3) and pro-thrombogenic (4**)** status, as well as the evidence-based association with the endothelial dysfunction and oxidative stress (5) supported the pathogenic relation to atherogenesis.

The existence of the syndrome has raised doubts and debates on its naming, components and pathogenesis from the very beginning. The dispute has even augmented to the attempt of approaching the MS as a disease with unique and generally accepted pathogenetic mechanism *(the* ***insulin-resistance*** *being, according to Reaven, the key mechanism)* (6) with a unitary curative and prophylactic strategy. The cardiologists had finally adopted the NCEP-ATP III guidelines for diagnosing (7) and quickly put it into practice, as it operated with easy to determine parameters *(abdominal circumference, BP, triglycerides, HDL-cholesterolemia and impaired fasting glycemia).*

By applying the ATP III criteria to a cross-sectional study, IIIrd NHANES determines a MS prevalence of 24% (1 of 4 persons) in USA, and therefore an extremely large proportion of population at high risk of diabetes and cardio- and cerebrovascular diseases, where the risk of individuals with MS to suffer a vascular accident *(stroke or AMI)* is 3 times higher than in those lacking the syndrome, the death risk carried by vascular accidents *(stroke or AMI)* is double *(8,9,10)*, and the risk to develop diabetes mellitus is 5 times higher (11) (or, 80% of diabetic persons die from cardio-vascular pathology); moreover, the

explosion in overweight in time has led to a MS prevalence increase from 23.1% (1988-1994) to 34 % (in 2010*)*, according to NHANES (12, 13).

The metabolic syndrome seems to be a major public health due to its

- major impact on the morbidity-mortality of obesity, atherosclerosis, diabetes mellitus and their complications;
- direct and indirect costs incurred *(medical care + economic loss consequent to temporary inactive periods, anticipated retirement and premature mortality);*
- behavioral changes incurred by an efficient prophylaxis *(nutrition, physical exercise);*
- need for involving governmental factors to ensure the logistic for these changes *(proper food, leisure parks, bike lanes etc);*
- need for involving the mass-media, school and family.

The huge stake of using the concept in setting preventive and therapeutic strategies has led to a great war in the medical media, with occasional polemic or sarcastic accents that have rarely been noticed in medical debates; we present below some eloquent headlines used by the opponents to this concept:

- Metabolic syndrome: clinical utility or futility; is this diagnosis necessary?- *(Reaven)* (14);
- Metabolic syndrome: a fata morgana?- *(Bakker et al)* (15);
- The myth of the metabolic syndrome- *(Gale)* (16);
- Metabolic syndrome . . . is dead - *(Jörgens)* (17);
- Should we dump the metabolic syndrome?: Yes . *(Gale)* (18);
- The concept of metabolic syndrome as a scientific instrument is a blunt sword *(Ritz)* (19);
- Metabolic syndrome - is it a syndrome? Does it matter? *(Kahn)* (20);
- The Metabolic Syndrome (Emperor) Wears No Clothes *(Kahn)* (21);
- The concept of the metabolic syndrome is it dead yet? *(Gupta et Poulter)* (22).

In reply, the metabolic syndrome supporters seem more balanced:

- Should we dump the metabolic syndrome? No. (*Alberti et Zimmet)* (23);
- Do not dump, but LEARN to recognize the metabolic syndrome *(Bense)* (24);
- The metabolic syndrome – revise the processes of care, don't dump the concept *(Holt)* (25);
- The metabolic syndrome still lives. *(Grundy)* (26);
- Metabolic Syndrome: older than usually assumed, but still too young to die *(Meisinger, Koletzko et Heinrich)* (27);
- The Metabolic Syndrome: perhaps an etiologic mystery but far from a myth (*Zimmet et Alberti)* (28).

We attempt to highlighting the main pros and cons:

Cons (21):

- Ambiguous or incomplete criteria and ambiguous reasoning of threshold values;
- The insulin-resistance as linking etiology is unclear;
- The insufficient prediction level of the syndrome, neither for CVD, nor for diabetes mellitus?
- The risk of association would not exceed either the sum of all component risks or even the risk of a single major component *(INTERHEART study)*;
- The lack of solid scientific evidence on clinical utility;

- The failure to establish a therapeutic strategy different from the approach of each component risk;
- The absence of a specific causal or pathogenetic treatment (the MS treatment is not different from the treatment of the sum of its components);
- Is it exaggerated to label over 25% of the population as ill (discriminatory? politically incorrect?).

It is also important that Gerald Reavan himself has reservations about on the practical utility of MS concept (14, 29)

To conclude, identifying each risk factor and a therapeutic approach for each of them would create a reasonable pragmatic conduct (30).

Pros

- The MS concept has already been proved as valid, solid and usefull in practice;
- MS should not be used as a risk quantification tool, but for the identification of high risk subjects who need an aggressive approach, both pharmacological and as a life style;
- The shared origin of MS components would require a holistic approach focused on behavioral changes (life style) at individual and population level, fact that allows the reduction of medication (31,32);
- The concept would also allow the medical approach of obesity, in addition to the purely cosmetic one *(Mc Guirre in 17)*.

To conclude, its usefulness would be sure in the awareness raising, education and motivation of high risk patients, targeting mainly the change in the life style.

Although (or because) the preventive power of using MS as a work tool equally targets DM and CVD, the diabetologists/endocrinologists (or, more precisely ADA and EASD) have alienate from this by publicly discouraging the use of MS concept *(33*), while most of the cardiologists and internists have enthusiastically adopted it, as AHA/NHLBI and ESC recommend it as a valid concept with real practical application. The strange polarization of the medical world, mainly by specializations (cardiologists versus diabetologists), made Scott Grundy consider the opposition of diabetology societies as the expression of a ***turf war*** subsequent the cardiologic societies entering a hunting ground the diabetologists consider it exclusively belong to them. Many people think about the media war around the metabolic syndrome as an exaggeration, or just a “a tempest in a teapot” or "a firestorm about nothing." (*Nathan in 17*). Finally, some contest MS as a scientific research tool, and others as a medical practice tool.

It is interesting that the Romanian endocrinologists and diabetologists accepted the use of the metabolic syndrome without aggressive disputes.

Although a truce has been sought for even from 2006 (accomplished only between IDF and AHA/ ESC), therefore a compromise solution that would not affect the aggressive and beneficient approach of risk factors, both disputants kept their ground, although there are many reasonable arguments among both diabetologists and cardiologists.

In 2006, in an attempt to harmonize the MS concepts, a consensus is reached between International Diabetes Federation Task Force on Epidemiology and Prevention, National Heart, Lung, and Blood Institute, American Heart Association, World Heart Federation, International Atherosclerosis Society and International Association for the Study of Obesity. They accept that the Metabolic Syndrome represents an

association (cluster) of risk factors for CVD and Type 2 DM that is more frequently met as the hazard may justify. These risk factors include: hypertension, dyslipidemia (hyper TG and low HDL-chol), increase in glycemia à jeun and central obesity. It has been accepted, in an attempt to unify the criteria, that the presence of 3 criteria out of 5 would allow the confirmation of the metabolic syndrome and, even if this should not be a compulsory criterion, the waist circumference is still a useful preliminary tool. It has been agreed the use of a unique set of cut-points, except for the waist circumference. To diagnose it, various criteria have been proposed for the definition of central obesity (compulsory component, with lower cut-points with ethnic specifications for IDF). It was also accepted that, in the interim, national or regional cut points for waist circumference can be used (31), *although certain studies state that* defining MS according to IDF criteria seems to be much better in CV risk predictors compared to that of NCEP-ATP III and NHLBI/AHA (35).

Although we agree with Scott Grundy that MS is still alive (26*)*, we have to accept that the researchers' interest in the metabolic syndrome has visibly reduced over the last years, and the topic seems to lose its importance. A good symptom for this is that ***The Journal of the CardioMetabolic Syndrome*** whose first edition seemed to be perfectly justified in 2006*(36)* ceased to exist. Another argument in this regard is the fading out of MS presence in the cardiovascular prevention guides; still, we have to note that ESC/EHS has relatively recently published a Guide dedicated to the metabolic syndrome and hypertension (37).

At the same time, we note the raise of surgeons' interest in obesity and MS, considering not only the impact of obesity and MS on the anesthetic and perioperative risks (materialized in heart, respiratory and renal complications, as well as in the increase in the hospitalization duration and cost) *(38)* but also the metabolic impact of surgical methods for treating obesity. Thus, the weight loss would be associated with reduced resistance to insulin, improved lipid profile and AT reduction *(39)*, meaning a reduced cardiovascular and diabetic risk, facts that justify the newer term of ***Metabolic Surgery***. The surgical therapy would be recommended for patients with diabetes mellitus or MS with BMI = 30-34.9 kg/m^2 (40).

The researchers' interest in the metabolic syndrome remains obvious in case of the researchers from developing countries usually confronted with tropical infectious diseases and malnutrition and where, implicitly, the metabolic syndrome represents a new challenge; this fact is visible both in the specialized Western publications *[Diabetes, Metabolic Syndrome and Obesity: Targets and Therapy (USA) Metabolic Syndrome and Related Disorders (USA), etc.]* and in the medical publications in this area *[Journal of Endocrinology and Metabolism (Malaysia). Diabetes & Metabolic Syndrome: Clinical Research & Reviews (India), Journal of Diabetes and Metabolic Disorders (Iran), etc.]*.

Although some studies suggested the existence of a common genetic ground (41,42), the attempt to clearly demonstrate this has failed and thus strengthened the position of the concept's opponents (43). The failure of the attempt to consider the metabolic syndrome as a generally accepted entity is owed, beyond any vanity, to the lack of any undeniable evidence that proves the existence of a superior risk by the asso-

ciation of the constituent risk factors compared to the separated risk of each risk factor, as well as a clear and unifying pathogenetic mechanism or a clear common genetic cause that would allow the synthetization of a unique medicine (44, 45). Nevertheless, the efforts to identify unitary pathogenetic mechanisms and to identify a therapy target still go on, as the sirtuins have been recently proposed (46).

O reasonable, pragmatic and acceptable opinion we would like to note in order to conclude is that of Dr. Darren McGuire (17), who considered the "metabolic syndrome as a useful construct that helps in a broad population of patients to identify those at increased risk of developing either diabetes or cardiovascular disease at a time when lifestyle intervention can be very useful". Emphasizing that "the presence of metabolic syndrome is where weight worries stop being cosmetic and start being medical", he considered that the metabolic syndrome is particularly applicable in the primary-care, on the one hand, because the diagnostic is simple and cheap, and on the other hand, because it makes the patient more aware of the importance of lifestyle changes.

0.000), egg white 19 cases (14.39%, p = 0.000), peanuts 10 cases (7.57%, p = 0,000), fish 8 cases (6%, p = 0.000), soy 6 cases (4.54%, p = 0.000), nuts 6 cases (4.54%, p = 0.000), wheat flour 5 cases (3.78%, p = 0.003), strawberries 2 cases (1.51%, p = 0.011) and rye flour 1 case (0.75%, p = 0.150) .

All allergens were statistically significant except for rye flour (p = 0.150) (fig. 2).

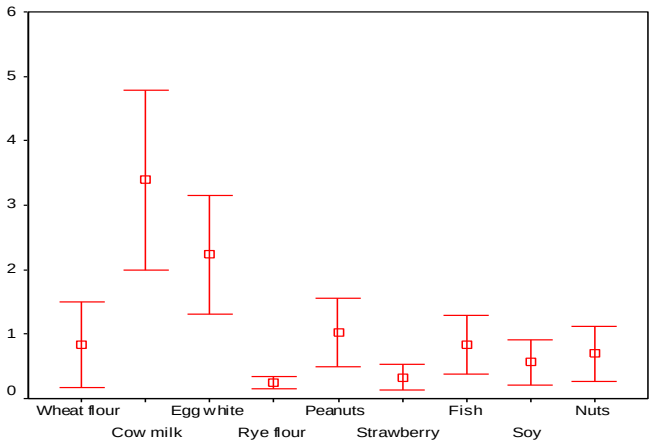

Fig. 2. The most common specific IgE allergens

In patients with low specific IgE levels but in which clinical manifestations and history were suggestive of allergy (47 cases - 35.60%), IgG4 antibodies against 20 food allergens were determined. Of these, 21 (15.9%) cases showed positive IgG4 levels against the following allergens: wheat flour (5 cases, p = 0.049), cow milk (3 cases, p = 0.072), egg white (2 cases, p = 0.061), peanuts (3 cases, p = 0.064), rye flour (2 cases, p = 0.040), strawberries (2 cases, p = 0.108), nuts (2 cases, p = 0.027), fish (1 case, p = 0.006) and soy (1 case, p = 0.087) (fig. 3). One patient presented mixed allergy to peanuts and nuts.

Of these allergens only wheat flour only (p = 0.049), rye flour (p = 0.040) and fish (p = 0.006) were statistically significant.

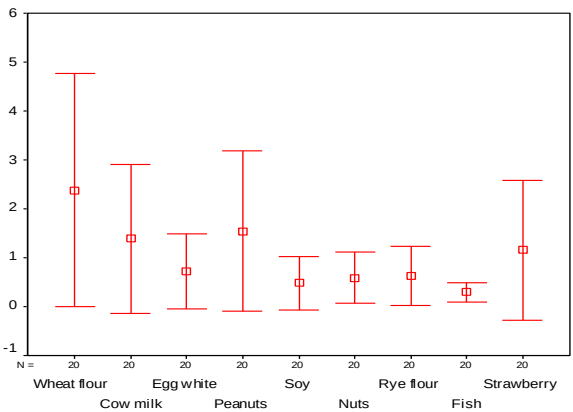

Fig. 3. The most common specific IgG4 allergens

In patients with positive IgG4 levels to different food allergens, 89% presented associated digestive and cutaneous symptoms, suggesting that the level of specific IgG4 antibodies is high in patients with gastrointestinal allergy, but has no predictive value.

Polysensitization to food and airborne allergens correlated with respiratory allergic manifestations (asthma and allergic rhinitis), occurring predominantly in the age group over 4 years, while atopic dermatitis was associated with food allergy in children under 4 years.

The reference values for specific IgG4 antibodies are listed in table I.

TABLE I
Interpretation of results for specific IgG4 antibodies

CLASS	REFERENCE VALUE	INTERPRETATION
0	<0.35 U/mL	**negative-** no IgG4 antibodies detected
1	0.35-0.7 U/mL	**borderline-** low level of IgG4 antibodies
2	0.7-3.5 U/mL	**positive-** moderate level of IgG4 antibodies
3	3.5-17.5 U/mL	**distinctly positive-** high level of antibodies
4	>17.5 U/mL	**Highly positive-** very high levels of IgG4 antibodies

DISCUSSION

Food allergy is defined as an immune response to food proteins affecting approximately 8% of children and 2% of adults (2), but it's the prevalence, as well as that of all allergic diseases is increasing.

In food allergy the mechanisms involved may be IgE or non-IgE mediated immune reactions. The immune mechanisms involved in non-IgE mediated reactions may be based on the participation of subtype 4 IgG antibodies. These types of IgG4 antibody mediated reactions are characterized by less severe and less specific symptoms, and have a late onset after the intake of the incriminated food (up to 72 hours).

There are several arguments supporting the involvement of IgG4 antibodies in non-IgE mediated food allergies: allergic reactions may occur independently of IgE specific antigen; subsequent decline of IgG antibody level when the incriminated food is removed from diet; specific IgG antibodies were identified in celiac disease, atopic eczema and in diseases associated with increased intestinal permeability (chronic inflammatory bowel disease) (3).

Besides hives and anaphylaxis triggered by IgE-mediated immune mechanisms, there are several cell-mediated diseases, such as food protein-induced eosinophilic esophagitis or enterocolitis. Non-IgE mediated food allergies that manifest with food protein-induced entercolitis syndrome or eosinophilic esophagitis are rare and have a favorable course on elimination diet (4).

Immune-mediated food allergies have to be distinguished from food intolerances caused by non-immune mechanism which are non-specific and their symptoms and those of irritable bowel syndrome often overlap (5). Allergic diseases by food sensitization are more common in the early years of life, their frequency decreasing with age, with the acquisition of tolerance

to food. Allergic manifestations with onset in the early years of life are the result of the interaction between genetic factors, environmental factors (artificial feeding, incorrect diversification, prolonged antibiotic therapy) and immaturity of the immune system in early childhood (6).

In our study group the diagnosis of food allergy was based on the criteria in international guidelines, suggestive clinical manifestations, thorough history, and positive levels of serum specific IgE and IgG4 against food allergens, positive skin tests, elimination diet, and oral loading test. The latter must be done under close medical supervision as it can cause such severe adverse reactions as anaphylaxis.

The analysis of specific IgE and IgG4 shows that 64.39% of the cases were IgE-mediated allergies and 15.9% IgG4-mediated allergies. The allergens most frequently involved were cow milk ($p = 0.000$), egg white ($p = 0.000$), peanuts ($p = 0.000$), wheat flour ($p = 0.003$) and fish ($p = 0.000$), in agreement with the data in literature (4, 7, 8). Correlation of skin test with specific IgE level showed a concordance between results. Skin tests have a sensitivity of 95% and a specificity of 50% (9). A negative skin test result has a high predictive value in children older than 1 year, while in children less than 1 year its negative predictive value is lower due to the particularities of cutaneous mast cells (small number and low reactivity). A positive skin test has a positive predictive value of only 50%. If history is not strongly suggestive of an allergy, the diagnosis should be confirmed by a challenge test (10).

With regard to egg allergy, recent studies estimate that it affects approximately 0.5-2.5% of children (11, 12), but there are studies reporting a higher percentage; thus, an Australian study suggests that 8.9% of children have allergic reactions to egg (13). In our study egg allergy is the second most common food allergy. Egg allergy is associated with a high risk of allergy to peanuts or other food allergens, atopic dermatitis, occurrence of respiratory allergy and asthma (14, 15, 16). The rate of resolution of egg allergy is slow; most studies show that tolerance to egg develops at age 3 (17), but there are studies suggesting that about half of children develop tolerance at age 12 (18). The latter study demonstrated persistent egg allergy in 42% of children in their teens, suggesting that the number of adults with egg allergy can increase with time, although current estimate of egg allergy among adults is 0.2% (19).

Factors predictive of the resolution of egg allergy are: initial reaction characteristics (isolated hives/angioedema versus other events), specific IgE level, intensity of skin prick test reaction, severity of atopic dermatitis, IgG4 level, response of interleukin 4 (IL-4). Of these, the first two are the most important predictors for resolution (11).

CONCLUSIONS

This study shows that IgE-mediated food allergies are more common, the highest percentage being recorded in children less than 4 years of age due to the interaction of genetic and environmental factors and immaturity of immune system in the early years.

IN MEMORIAM

PROFESSOR GEORGETA DATCU, M.D., Ph.D.

(27 August 1939-10 August 2015)

The academic community of "Grigore T. Popa" University of Medicine and Pharmacy Iasi expressed by the voice of 1962 promotion its deep regret for unexpected loss of our distinguee colleague Professor Doctor Georgeta Datcu, teacher and head of the Ist Medical Clinic for more than four decades.

Originating in Bacau in a family of intellectuals, his father dr. Demostene Teja being a renowned radiologist and her mother being pharmacist, she naturally oriented toward medical career. High school graduating with honors she benefited a merit bachelor being admitted without examination and between 1956-1962 pursued the General Medical faculty courses distinguishing herself for intellectual qualities and passion of perfection in medical profession. As colleague and chief of our group she proved modesty and diplomacy, never wanting social roles, her politics being only school performance.

Due to its endowment but also to the great generation of masters we have benefited: I Iancu, I. Nițulescu, Gh. Chipail, I Enescu, Vl. Butureanu, Maria and O. Franke, Th. Economu i.e., she graduated with one of the highest accolades.

She became by competition apprentice (1960) and *house officer* (1962) carrying out her training in prestigious clinics mainly in internal medicine services.

In 1962 she sustained the licence thesis intitled *"Pseudartrosis of the rachisyntesis graft in Pott's disease in children"* conducted in Pediatric Surgery Clinic and appreciated with maximum qualifier.

In the Ist Medical Clinic she was spotted and guided by Professor Constantin Negoiță, known for the rigor of its staff selection who was her mentor and role model for entire career, dr. Georgeta Teja being the first in a series of valuable graduates, four of which becoming later heads of clinics. Therefore in 1965 she became jr assistant of this clinic where will activate for 44 years being successively promoted assistant (1968), lecturer (1983), associate professor (1990) and professor (1994). She became also registrar (1968) and consultant in internal medicine (1978) and cardiology (1983).

She led the clinic for 15 years until her retirement with professionalism, strictness and balance maintaining its excellence and reputation.

As practician outside her encyclopedic knowledge and holistic approach of the suffering, Professor Datcu had particular clinical feel destined only to "true doctors" always surprising by the finesse and accuracy of diagnosis and optimal therapeutic solution

Although her priority was competence in cardiology, like her illustrious predecessors Professors Bacaloglu, Niculescu, Tudoranu and Negoiță, Professor Datcu

demonstrated broad knowledge in other specialties of internal medicine.

She gave equal importance to teaching activity through clinical internships and demonstrations filled of attainments, dedication and patience stored in the memory of students but also of young colleagues, residents or physicians in training, all of them decisive benefiting in their education and perfection.

Her lectures have excelled by sober style without pedantry, logic and systematized, oriented to practice, all dressed in an elegant, worship language, always appropriate to the audience. Like her mentor, Professor Datcu had an impressing scientific activity not by the number but by the value of its works. Most of publications realized together with Professor Negoiță and collaborators from the clinic include clinical trials or casuistry published in specialty literature. As a tragic coincidence our last common work treating cardiothyreosis was printed quite in her dying day.

In 1984 she sustained her doctoral thesis having as theme the *"Study of capacitant vessels in systemic arterial hypertension"* headed by Professor Negoiță completing an original research spread over several years enjoying unanimous appreciations. In 1996 Professor Datcu became Ph.D. superviser in internal medicine and cardiology directing with her proverbial competence and exigency a number of theses.

Its main medical writings still remain chapters included in the treaty of Medical Clinic under the editorship of Professor Negoiță in 1995 (bronchiectasis, bronchial asthma, bronchopulmonary carcinoma) and those under editorship of her colleague and husband Professor Mihai Dan Datcu *"Clinical confrontations - commented cases"* 2003 and *"Controversies and diagnostic errors in cardiology"* 2009, all of great use and practical interest for students, residents but also specialized doctors.

She also participated actively and consistently with papers, reports or in quality of chairman at numerous scientific meetings with topics of internal medicine and cardiology, either autochthonous - some organized in Iasi – either abroad, established itself as one of the most prominent contemporary personalities of specialty Colleague and friend for almost sixty years I could appreciate the intelligence and culture not only professional of Professor Georgeta Datcu, her great character full of frankness, honesty, loyalty and altruism, all wrapped in a mantle of humor and Moldavian kindness.

Her disappearance - the first female professor of internal medicine in our country - is a heavy loss both for the Romanian medical world and for collaborators, colleagues and its friends.

God rest her soul….

Dr. Mihai Radu Diaconescu,
Professor of Surgery

LAUDATIO

PROFESSOR ALLA VÂȚĂ, M.D., Ph.D.

A CAREER OF SUCCESS

Prof. Alla Vâță, PhD is one of the most important Romanian specialists in the field of infectious diseases. A genuine and dedicated scholar, she is endowed with a rare intelligence. She has always enjoyed the respect and admiration of the whole medical community. She is admired for her excellent professional training that became obvious whenever she presented her opinions about a diagnosis or whenever she taught her undergraduate and graduate students. Her lectures captivated the audience. She is a modest lady and an exact and patient scientist. Prof. Alla Vâță led with a firm hand the Iasi Infectious Diseases Hospital. She was also a remarkable researcher in her field.

She was born in 1920 in Kishinew, where she completed her secondary studies. In the period 1940-1945 she attended the Iaşi Faculty of Medicine**.** Her professors were among others**:** Al. Țupa, C. C. Dumitriu, I. Enescu, I. Tănăsescu, D. Cornelson, all of them outstanding scientists in their field.

In 1945, after a competition she was accepted in the externship program at the Hospital of Infectious Diseases, led by prof. Maria Franche, PhD, who became Mrs Vâță"s model throughout her life. She started her academic career in 1946 at the same clinic. A brilliant career followed: junior teaching assistant, assistant lecturer, lecturer (1952), associate professor (1961), professor (1970). In 1963 she defended her PhD in medical sciences, complemented in 1972 by the highest Romanian academic degree that was awarded after defending the second doctoral dissertation. Prof. Dr. Alla Vâță has been an honorary Member of the Academy of Medical Sciences since 1996.

In 1981 she became consultant on the staff of the Hospital of Infectious Diseases. During her teaching career she supervised 16 doctoral dissertations at the Iasi ″Gr. T. Popa″ University of Medicine and Pharmacy. During this prodigious career she was driven by the desire for continuous improvement despite the isolation of Romania from the western world.

Prof. Dr. Alla Vâță enjoyed a remarkable teaching career**.** She used to teach the 6th year medical students and postgraduates, being admired and respected by all her students and colleagues.

She taught a course of lectures on infectious diseases. Moreover, she managed to create a school of highly trained specialists in infectious diseases, many of them becoming in their turn professors in this field (St. Dumitriu, E. Brauner, V. Luca), senior consultants (dr. E. Beşleagă, dr.C. Scurtu), and heads of department from of hospitals all over Romania. All of them were able to solve the most difficult problems this specialty was faced with at that time.

She was a remarkable manager, leading

IMPLICATIONS OF GHRELIN AXIS IN BREAST CANCER - REVIEW

IMPLICATIONS OF GHRELIN AXIS IN BREAST CANCER - REVIEW (Abstract): Breast cancer is, by far, the most frequent cancer among women and many factors influence the physiological and pathological growth and development of the mammary gland. There is developing evidence that the hormone ghrelin, known for the growth hormone releasing effect and food intake modulator, could also play a role in the pathogenesis of breast cancer and may represent a new diagnostic marker and a potential therapeutic target. We performed a PubMed Database search of relevant studies and ten papers were included in our systematic review. Ghrelin axis seems to be definitely involved in the pathogenesis of breast cancer, although a precise role has not been yet established. In order to verify the precise role of ghrelin axis in breast cancer further studies with larger populations are necessary that should include the analysis of metabolic, genetic and environmental factors which are expected to influence the results. **Keywords:** GHRELIN, BREAST CANCER, NOVEL THERAPEUTIC TARGETS

Breast cancer is, by far, the most frequent cancer among women with an estimation of 1.67 million new cases diagnosed in 2012 (25% of all cancers). Also it is the most frequent cause of death in women in less developed regions, while in more developed regions it is now the second cause of death (after lung cancer), ranking as the fifth cause of death from cancer overall (522,000 deaths) (1).

There are many factors that influence physiological and pathological growth and development of the mammary gland. Endogenous hormones (sex hormones, growth hormone axis), reproductive factors (lower parity, older age at first giving birth, younger age at menarche, older age at menopause), oral contraceptives and hormone replacement therapy, family history and genetic factors (BRCA1 and BRCA2 mutations), alcohol and smoking, diet, overweight and obesity are known to be risk factors in breast cancer (2).

There is developing evidence that ghrelin, known for the growth hormone (GH) releasing effect and food intake modulator (3) could also play a role in the pathogenesis of breast cancer and may represent a new diagnostic marker and a potential therapeutic target.

THE GHRELIN AXIS

From its discovery in 1999 (3), further studies revealed that ghrelin axis is not simple, but a complex, diverse system, regulated at several stages, which determines diverse transcripts and proteins with multiple functions, many of them still likely to be discovered.

Ghrelin is a unique 28-aminoacid (AA) peptide containing an n-octanoyl group on the serine in position 3 and it is the natural ligand for the growth hormone secretagogue (GHS) receptor (GHS-R) (3, 4, 5). Circulating ghrelin consists of more than 90% of des-acyl ghrelin and less than 10% acyl ghrelin (6).

The human ghrelin gene is localized on the chromosome 3p25-26 (7). Fig. 1 summarizes the steps which lead to the production of the different ghrelin gene products. Preproghrelin mRNA is a transcription isoform of the ghrelin gene that leads to the translation of preproghrelin (117 AA) (3). Preproghrelin contains an N-terminal signal peptide (23 AA) that is cleaved from the polypeptide to form proghrelin (94 AA). Proghrelin is further processed (mainly by prohormone convertases - PC1/3) to produce the ghrelin peptide (28 AA) (8,9).

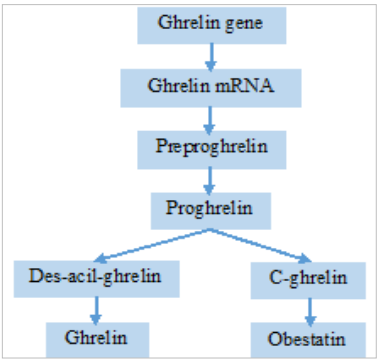

Fig. 1. Sequential steps of the production of the major ghrelin gene-derived products

The cleavage of the ghrelin molecule from proghrelin produces C-ghrelin (66 AA), which is then further cleaved to form obestatin (23 AA). Both C-ghrelin and obestatin circulate in human plasma (10).

Proghrelin can be posttranslationally modified with the addition of an octanoyl group to the serine 3 residue of ghrelin, through an acyl-bond, by the enzyme ghrelin O-acyltransferase (GOAT) (11,12). Not all circulating ghrelin is octanoylated and the majority of plasma ghrelin is actually the non-acylated form termed des-acyl ghrelin (27 AA). Acyl-protein thioesterase 1 (APT1) has been described to convert ghrelin to des-acyl ghrelin in the plasma (13).

Ghrelin can be also acylated with groups other than octanoic acid, depending on dietary modifications, such as decanoic acid resulting in a decanoylated form termed D-ghrelin (14).

The ghrelin receptor belongs to G-protein coupled receptors (GPCR) superfamily. The *GHSR* gene is located on chromosome 3q26.2 (15). There are documented two splice receptor variants, type 1a (GHSR1a) and type 1b (GHSR1b). GHSR1a is known as the functional form of the receptor that mediates many of the ghrelin effects. GHSR1b is a truncated form and has been considered as a non-functional receptor because ghrelin does not bind or activate this receptor (16).

A range of alternative splice variants arise from the ghrelin gene, many of which may encode novel peptides. Although their receptors have not yet been identified, they have already proven to be active, having intriguingly subtle but opposite physiological actions to ghrelin (17, 18, 19, 20).

PHYSIOPATHOLOGICAL ROLES OF GHRELIN WITH IMPLICATIONS IN BREAST CANCER PATHOGENESIS

Ghrelin and ghrelin-receptors are expressed in a wide range of normal and tumor tissues suggesting it has many physiological functions and pathological implications. Ghrelin can exert its effects through endocrine or autocrine / paracrine actions.

The major role of ghrelin is to stimulate GH secretion, via its binding to GHSR1a on the pituitary somatotropic cells, acting in synergy with GH-releasing hormone (GHRH), thus activating GH/IGF-1 axis with major proliferative effect on both normal and tumor cell types (21, 22). Ghrelin is also able to stimulate the pituitary secretion prolactin (PRL) and adrenocorticotropic hormone (ACTH) inducing further cortisol release (23).

Ghrelin is also a major food intake modulator stimulating appetite by central and peripheral pathways and *via* the vagus nerve. Ghrelin is secreted in a pulsatile manner increasing before the onset of meal, during fasting, and decreasing after feeding (24). The clinical application of these effects have been investigated in both eating disorders and muscle wasting conditions, including obesity, cachexia and sarcopenia, conditions that are also encountered in the tumoral genesis and evolution of breast cancer (25).

Besides these two major effects, ghrelin has a multiplicity of other physiological roles affecting energy and glucose homeostasis, gastrointestinal, cardiovascular, pulmonary systems, immune function and bone physiology (25).

Ghrelin is involved in long-term weight regulation fluctuating in a compensatory manner to body weight modifications, thus decreasing with weight gain (overfeeding, high fat diet) and conversely increasing with weight loss (food restriction, cachectic conditions like in advanced cancers) (25).

In connection with body weight and body fat weight it was shown that ghrelin and des-acyl ghrelin may inhibit aromatase expression and activity in human adipose cells. This is a very important effect because aromatase converts androgens into estrogens and its expression within adipose stromal cells is believed to be the major driver of estrogen-dependent cancers in older women (26).

Concerning glucose homeostasis (with implications in insulin/IGF-1 axis), ghrelin was shown to decrease insulin sensitivity depending on the acyl ghrelin/des-acyl ghrelin ratio as acyl ghrelin determines insulin resistance, while des-acyl ghrelin neutralizes this effect (27).

Ghrelin also controls several aspects of female reproductive system inhibiting hypothalamic gonadotropin-releasing hormone (GnRH) and of both LH and FSH secretion (28, 29, 30).

More direct effects in cancer pathogenesis were studied and showed that ghrelin is involved in a number of processes associated with cancer progression, including cell proliferation (probably *via* MAPK / ERK1/2 pathway), cell migration and invasion, the inhibition of apoptosis and ghrelin could play a role in angiogenesis and cancer-related inflammation (31).

GHRELIN AXIS AND BREAST CANCER

Although it is known that many tumors express members of the ghrelin axis, their role in cancer has not been extensively studied. Searching PubMed database on the implications of ghrelin axis in breast cancer

(excluding articles on orexigenic effect of ghrelin), ten original articles were found concerning this subject. A similar search was performed in 2012 by Stefanaki et al (32) and our systematic review is updated with the latest studies results.

The first study to show that ghrelin has a potential clinical application in breast cancer was performed by Cassoni *et al* in 2001 (33). The study demonstrated that there are specific receptors present in human breast carcinomas, in both estrogen-dependent and estrogen-independent breast cancer cell lines, which bind natural and synthetic GH secretagogues, thus proving they may have other biological activities, independent of their GH releasing effect. The same study concluded that these receptors were also having an inhibitory action on breast cancer cell proliferation *in vitro*, probably *via* activation of binding sites, different from GSHR1. Additionally, the entity of the binding was independent from the histological type of the tumor, stage, estrogen receptor status, proliferative index and whether patients where in pre- or post-menopause. However, it was positively correlated to the grade of tumor differentiation, in a way that well-differentiated carcinomas showed a higher GHS binding than moderately and poorly differentiated carcinomas (33).

The following study was performed by Jeffery *et al* in 2005 (34). The aim of this study was to investigate ghrelin expression in breast cancer tissues and cell lines and to examine the effect ghrelin has on breast cancer cells proliferation *in vitro*. According to their results, ghrelin plays a role in breast cancer by stimulating cell proliferation in both estrogen-dependent and estrogen-independent tumors. They reported that the truncated isoform GHSR1b is highly expressed in breast cancer tissue with negligible expression in normal breast specimens. Taking into account that GHSR1 is expressed in both normal and cancer tissues and cell lines, this may suggest that GHSR1b could represent a new marker for breast cancer. In their study, Jeffery *et al* also described the expression of exon 3-deleted preproghrelin (a human proghrelin isoform), which encodes mature ghrelin and a novel C-terminal peptide. This peptide was found to be highly expressed in the estrogen-independent cell lines, but also in the glandular epithelium of high-grade cancer tissue, exhibiting the highest immunoreactivity and thus indicating it may play a functional role in breast pathogenesis (34).

In 2006, Wagner *et al* (35) investigated the effect of a total 12 single-nucleotide polymorphisms and 3 dinucleotide repeats in the genes encoding *GHRH*, *GHRL* and somatostatin (*SST*) and their receptors (*GHRHR*, *GHSR*, *SSTR2*) on the risk of breast cancer. The results demonstrated that the *GHRL*, *GHRHR*, *SST* and *SSTR2* gene polymorphisms may contribute to a decreased breast cancer risk and this would be consistent with a decreased activity of the IGF-1 pathway (35).

Another study was performed by Dossus *et a*l in 2008 (36), which investigated the association of 15 genetic variants in the *GHSR* and *GHRL* genes with breast cancer risk, circulating IGF-1 and IGFBP-3 levels, and anthropometric measures. In their study, GHRL SNP rs171407 was found to be associated with an increased breast cancer risk (20%), with a greater height (+0.4%) and with a lower BMI (-1.9 %). Similarly, GHSR SNP rs572169 was also associated with increased breast cancer risk (20%) and greater height (+0.4%), but not

with BMI. Another GHRL SNP - r3755777 - was associated with higher circulating IGF-1 levels. The findings of Dossus *et al* study might reflect an effect of these polymorphisms in *GHSR* and *GHRL* genes on breast cancer through the GH axis, independently of BMI or obesity and consequently independently of the ghrelin action on appetite and food intake (36).

In the same year, Feigelson *et al* (37) conducted a case-control study among postmenopausal women to establish whether genes associated with obesity increase the risk for breast cancer. Among these genes was also *GHRL* gene and the study found no association between the gene and breast cancer risk (37), contrary to previous study of Dossus *et al* (36).

Also in 2008, Ordway *et al* (38) conducted a study on DNA methylation alterations in breast cancer that identified a single locus within the promoter region of *GHSR* gene that is hypermethylated, which is capable of distinguishing infiltrating ductal breast carcinoma from cancer-free breast tissue with a sensitivity and specificity of 90% and respectively 96% (38).

Later, in 2011, Gahete *et al* (39) showed than In1-ghrelin - a variant transcript processed from the *GHRL* gene - was expressed about 8 times higher in breast cancer samples compared to normal mammary tissue. The levels of In1-ghrelin expression was strongly correlated in breast tumors with GOAT, GHSR-1b, cyclin D3 (a proliferation marker) and Ki67, but not with native ghrelin or GHSR-1a, thus suggesting a possible relevant role in the pathology of breast cancer. Further, the In1-ghrelin over expression in estrogen-dependent breast cancer cell lines caused increased proliferation rate suggests that the blockade of In1-ghrelin variant may have some therapeutic benefit (39).

In the same year, Grönberg *et al* (40) conducted a study to evaluate the potential biological and prognostic role of ghrelin and obestatin expression in invasive breast cancer. The results showed that ghrelin and obestatin were positively correlated to ER expression and negatively to proliferation rate, tumor size and to the Nottingham histologic grade (NHG) status. Also ghrelin expression was associated with a prolonged survival, which is consistent with the negative correlation to tumor grade, size and proliferation rate. Further, the results showed that tumors expressing ghrelin had 2.5-3 times lower risk for recurrence or breast cancer-specific death than those lacking ghrelin expression, proving a potential role of ghrelin as a prognostic marker in breast cancer. Even though ghrelin and obestatin were significantly correlated to each other, obestatin did not provide any prognostic information (40).

Botla *et al* (41) performed in 2012 a study aimed to identify methylation variation that could differentiate between breast cancers and other breast tissue. They have established a signature associated with two genes - *GHSR* and *SFRP2* (associated with poor patient survival) - which exhibited significant hypermethylation in cancers suggesting an epigenetic defect. Concerning diagnosis, the *GHSR* pattern demonstrated a very high sensitivity and specificity of 89.3% and 100%, respectively. To date, this represents the highest combined sensitivity and specificity for a DNA-based biomarker in breast cancer reported (41).

CONCLUSIONS

In this systematic review we tried to identify the implications of ghrelin axis in breast cancer. The ghrelin axis seems to be

definitely involved in the pathogenesis of breast cancer, but a precise role is not yet established. Studies performed up to date are not sufficient to support that ghrelin itself should be used in current management strategies, but they show much promise concerning early detection, prognostic and therapy in breast cancer.

Further studies with larger populations are necessary that should include the analysis of factors (metabolic, genetic and environmental) which are expected to influence the results, in order to verify the precise role of ghrelin axis in breast cancer.

NEWS

SUDDEN DEATH OF AN INFANT WITH CORONARY INVOLVEMENT DUE TO TAKAYASU ARTERITIS

Takayasu arteritis is an inflammatory disease that involves large vessels, predominantly the aorta and its main branches. This disease is much more common in females than in males, and the age of onset usually ranges between 10 and 30 years old, but it has been reported in children as young as 2 years of age. Coronary artery lesions are occasionally found in adult patients with Takayasu arteritis and rarely in younger children. Myocardial infarction or heart failure due to coronary involvement can be one of the potentially fatal complications in this disease. Usually, the involved arteries, aorta and its main branches, were thickened and stenotic. In the reported case, the ascending aorta was thickened and showed ostial stenosis in the coronary arteries bilaterally. The proximal segment of the left and right coronary arteries showed approximately 60% and over 90% occlusion, respectively. Microscopically, the intima was thickened due to an increase of intimal cells and fibers, and the adventitia showed thickening with fibrosis. In addition, remarkable infiltration of inflammatory cells, including multinuclear giant cells phagocytosing fragmented elastic fibers, and destruction of elastic fibers were observed in the media. However, Takayasu arteritis has not been recognized as a cause of sudden coronary death in infants. This report presents a case of sudden infant death due to severe stenosis of the left and right coronary arteries caused by Takayasu arteritis, which had not been diagnosed before death. In conclusion, Takayasu arteritis can be a life-threatening condition even in infants. There may be other similar cases that were unrecognized at autopsy in children with sudden unexpected death that are needed to be diagnosed (Wang EL, Sato Y, Kitamura O, et al. Sudden death of an infant with coronary involvement due to Takayasu arteritis. Cardiovascular Pathology 2013, 22: 109–111).

CURRENT CONCEPTS IN MINIMAL HEPATIC ENCEPHALOPATHY (Abstract): Minimal hepatic encephalopathy (MHE) defines the presence of neurocognitive impairments in patients with cirrhosis or portal-systemic shunting that show a normal neurologic and psychiatric status on clinical examination. Although ammonia has the central role in MHE pathogenesis, factors such as infection, oxidative stress, manganese or intestinal bacterial overgrowth contribute to the development of the neurocognitive deficits associated with this disease. Many methods have proven useful in identifying MHE but because of the major drawbacks (standardization requirements, high price, sophisticated equipment, and limited access) a gold-standard test is still missing. Although beneficial, the treatment of MHE is not routinely recommended and should be taken into consideration in patients at risk for accidents and in those with cognitive complaints or decline in work performance. **Keywords**: MINIMAL HEPATIC ENCEPHALOPATHY, LIVER CIRRHOSIS

Hepatic encephalopathy (HE) is a brain dysfunction caused by liver failure and/or portosystemic shunts (PSS). The clinical picture of HE includes neuropsychiatric abnormalities, which may vary from subclinical manifestations to coma (1). Factors such as multifactorial etiology, polymorphism of clinical manifestations, oscillating evolution, and the wide variety of precipitating factors constituted prerequisites for developing a guideline for classification, diagnosis and treatment of this pathology. The American Association for the Study of Liver Diseases and the European Association for the Study of the Liver established a working group that put forward guidelines regarding the nomenclature used for defining and systematizing HE based on clinical manifestations (fig 1).

The current standardization individualizes Minimal Hepatic Encephalopathy (MHE) as a separate entity together with the old West Heaven criteria. According to the nomenclature used by the International Society for the Study of Hepatic Encephalopathy and Nitrogen Metabolism (ISHEN), MHE and grade I HE are included into covert HE (1, 2). MHE is defined by neurologic and psychiatric status within normal limits during clinical examination, but with neurocognitive deficits detectable by psychometric or neuropsychological testing (3). Neurocognitive abnormalities include impaired attention, deficits in fine motor skills, disorders of the visual-spatial perception and altered executive functions (4, 5).

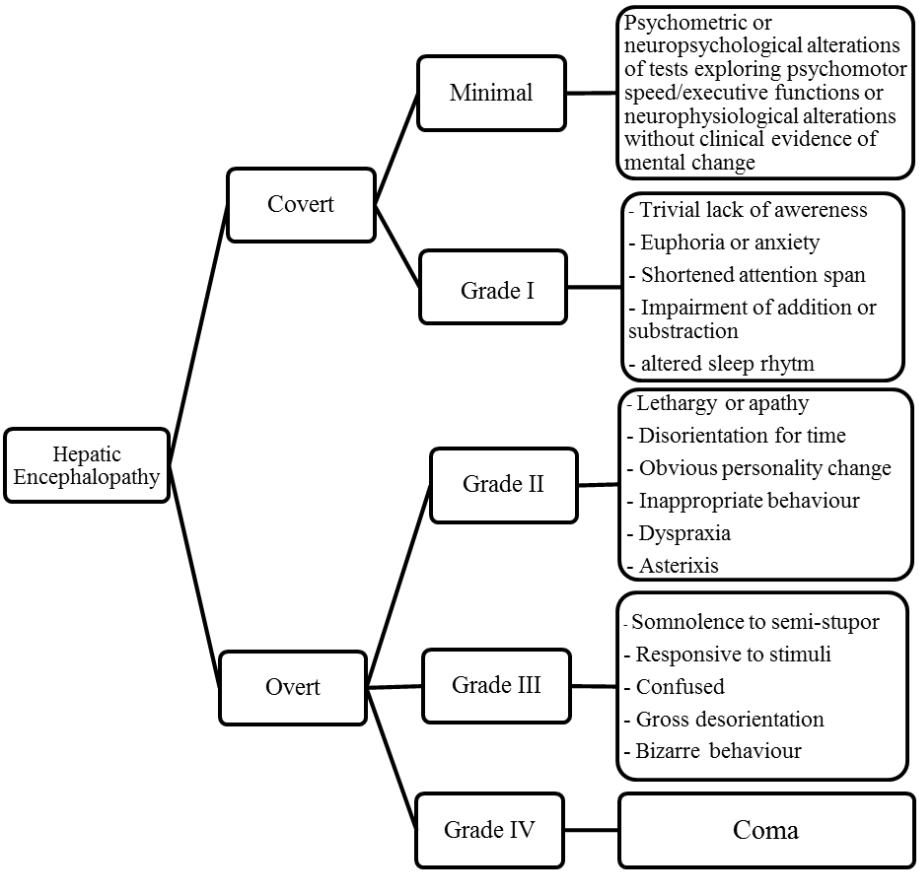

Fig. 1. Classification of Hepatic Encephalopathy adapted from Vilstrup et al. - Practice Guideline by The European Association for the Study of the Liver and The American Association for the Study of Liver Diseases (1)

PATHOGENIC THEORIES

The mechanisms involved in MHE pathogenesis are not fully understood, but even in 2014 ammonia continues to play the central role. Recent studies have pointed to the importance of additional factors, such as inflammation, oxidative stress and intestinal bacterial overgrowth, in generating neuropsychiatric abnormalities in this category of patients (6).

Ammonia has a decisive role in the pathogenesis of MHE. Physiologically, ammonia is converted to urea in the liver. This metabolite is water-soluble and it is excreted from the body by the kidneys through urine. In patients with chronic liver diseases or portosystemic shunts, this metabolic pathway is compromised and ammonia degradation occurs primarily in muscle cells, and in the cells of the central nervous system. The extrahepatic catabolic process makes use of the amino-glutamic acid to transform ammonia into glutamine (7, 8). MHE is a form of gliopathy caused by type II astrocytes, the only cells at brain level containing glutamine-synthetase that can

metabolize ammonia. The intracellular glutamine concentration within astrocytes increases proportionally with the level of ammonia in the blood. An active osmolyte, glutamine draws water inside the atrocytes, determining their increase in volume, while causing the secondary development of brain edema and intracranial hypertension (9, 10). This theory is supported in a study by Tanigami et al. performed on animal models, which revealed the lack of astrocyte volume expansion following the administration of methionine-sulfoximine (glutamine-synthetase inhibitor) (11).

Secondary to prolonged exposure to high ammonia concentrations, astrocytes undergo morphological and functional changes. During this stage, brain cells undergo a transformation process turning into type II Alzheimer atrocytes, characterized by large nuclei, prominent nucleoli and chromatin marginal arrangement (12). In order to compensate for the increase in volume, the astrocytes release osmotic-active molecules, such as myo-inositol and taurine (13, 14). According to a study by Shawcross et al. (15), the low levels of intracellular myo-inositol are associated with increased risk of neurological impairment. Glutamate transporters situated along the astrocyte membrane are inactivated and the activity of post-synaptic receptors for glutamate is inhibited. These functional transformations determine alterations of the neuronal function, reducing the conduction of nervous impulses (16, 17). Ammonia alters the function of the hematoencephalic membrane and determines the decrease of small and medium chain amino-acids and an increase in the inflow of neutral long-chain and aromatic amino-acids. Secondarily, the intracerebral synthesis of catecholamines (serotonin and dopamine) is reduced, with inhibitory effects on neurotransmission (18, 19).

Infection and inflammation. Although ammonia is an important factor in MHE pathogenesis, 10% of HE patients have normal levels of ammonia in the blood (20). Except for ammonia, there are other neurotoxic compounds derived from the bacterial metabolism showing high serum levels in patients with chronic liver diseases: phenols and mercaptans. Produced by bacteria in the bowel, these substances are not catabolized in the liver due to the impaired liver function and they are transported to the brain, where they exert their neurotoxic effect (21). A recent study by Bajaj et al. emphasizes the important role of acute bacterial infections and associated inflammation in the development of neuropsychiatric anomalies in patients with HE. The authors identified imbalances in the intestinal microbiome of cirrhotic patients. The presence of certain bacterial families (Alcaligeneceae, Porphyromonadaceae, Enterobacteriaceae) in the stool of patients with overt hepatic encephalopathy (OHE) was associated with systemic inflammation and the presence of cognitive deficits (22). Moreover, inflammation and inflammatory mediators enhance the negative effects that ammonia has on the central nervous system (23). Studies on astrocytes by Alvarez et al. and Rama Rao et al. demonstrated an increase in mitochondrial permeability under the influence of ammonia, TNF-α, IL-6, IL-1β and IFN-γ. High levels of IL-6 and TNF-α proinflammatory cytokines were found in the blood of patients with MHE (24, 25).

Oxidative stress. Molecular studies on rats revealed a rise in the synthesis of reactive oxygen species (ROS) and reactive nitrogen species (RNS) by the astrocytes

following exposure to ammonia, pro-inflammatory cytokines or benzodiazepines (26, 27, 28). On the other hand, Reinehr et al. revealed an increase in astrocyte volume when exposed to ROS and RNS (29). According to the hypothesis of Albrecht and Norenberg, glutamine determines an enhancement of the oxidation processes in the astrocytes through intra-mitochondrial release of ammonia. It later favors the creation of ROS and RNS through calcium-dependent reactions. Moreover, ROS mediates tyrosine nitration reactions. Tyrosine nitrate alters the permeability of the hematoencephalic membrane, favoring the expansion of the astrocyte volume and cerebral edema (30).

Manganese is a neurotoxin that accumulates in the central nervous system (CNS) preferentially in the basal ganglia and may be pointed out by magnetic resonance imaging (MRI) (31). In a MRI study on cirrhotic patients with portacaval anastomoses or transjugular intrahepatic portosystemic shunt (TIPS), Spahr et al. revealed a hypersignal at basal ganglia level in 88% of the patients. Additionally, 89% of the patients presented extrapyramidal symptoms and 67% of patients had increased levels of manganese in the blood. These findings are reversible after the normalization of liver function (32,33). Manganese homeostasis alterations may contribute to the development of cognitive deficits present in the clinical picture of patients with liver cirrhosis (31, 32, 33).

Neuromodulators. Ammonia and manganese determine increase in the density of peripheral type benzodiazepine receptors (PBR) in the brain. These receptors regulate the synthesis of neurosteroid hormones like tetrahydro-progesterone (THP) or tetra-hydroxycorticosterorne (THDOC) by the astrocytes and are present in high numbers in the CNS of patients with MHE. THP and THDOC potentiate the activity of gamma-aminobutyric acid (GABA) receptors, with inhibitory effect on the nerve conduction in the CNS (34, 35). This theory might explain the impairment of fine motor skills and coordination or the psychomotor disorders seen in patients with MHE (36, 37).

*Intestinal bacterial overgrowth (IBO)***.** A study on patients with MHE by Liu et al. revealed changes in the intestinal microbiome with an increase in the number of urease producing bacteria. Therapeutic intervention (synbiotic treatment) was associated with improvement of bowel flora imbalances, as well as better psychometric tests results. (38). In another study, Gupta et al. revealed a high prevalence of IBO in patients with MHE (38.6%) (39).

CLINICAL AND SOCIOECONOMIC IMPLICATIONS

MHE has a negative effect on the quality of life and determines alterations of the psychomotor skills and the ability to process information (40, 41). Prasad et al. revealed the impairment of daily activities such as social interaction, emotional behavior, reading, alertness and recreation periods in patients with MHE (42). Moreover, sleep disorders constitute a frequently met feature associated with chronic daytime fatigue and circadian rhythm disorders (43, 44). Weissenborn et al. outlined the negative impact that MHE exerts over short-term memory. Memory disorders have also been associated with attention and visual perception deficits (45).

Particular aspects of cognitive deficits in MHE determine differences in the ability to work in various professions. Cirrhotic patients involved in professions that require

constant vigilance and coordination (e.g. operators of industrial machinery or drivers) are more severely affected by MHE compared with the patients dealing with predominantly intellectual or verbal tasks (e.g. administrative or executive functions) (46). MHE may adversely impact the socioeconomic status of patients by reducing workplace performance. Approximately half the patients diagnosed with MHE do not have a job (47). The decrease in workplace performance and the diminution or the absence of a salary involves substantial moral and material losses for the individual (46). MHE affects both the individual and the society, generating high costs through repeated hospitalizations and treatment, in the evolution towards OHE development (48). Besides affecting the quality of life, MHE patients have an increased risk of progression to OHE. The patients constitute a potential danger both to themselves and to the wider community (49). Attention deficits, memory alterations and persistent fatigue associated with MHE contribute to impairment of driving abilities and an increased number of driving errors (exceeding the permissible speed, illegal turns, or accidents) (50, 51, 52).

Although MHE represents the initial stage of the neurocognitive impairment spectrum associated to cirrhosis, some studies correlate it with increased mortality (53). In a study by Dhiman et al., MHE patients showed faster progress towards grade I HE or OHE, and an increased rate of progression to liver failure. In addition, the study showed higher mortality rates in patients with MHE as compared to those without MHE (39.1% vs. 22.9%). (54)

DIAGNOSIS

MHE diagnosis requires the use of neuropsychological and/or neurophysiological tests in order to document neurocognitive alterations occurring in patients with chronic liver diseases or PSS. Standard clinical examination does not reveal any neurological anomalies or mental disorders. In what follows, we will point out MHE diagnosis criteria adapted from Simon-Talero et al.: diagnosis of a disease that can cause MHE - cirrhosis, PSS or portal vein thrombosis; normal neuropsychiatric status on clinical examination; absence of grade I HE or OHE; documentation of neurological alterations by formal neuropsychological assessment, neuropsychological tests, computerized tests or neurophysiological tests; the exclusion of other factors or diseases that can cause neurological impairment - metabolic, cerebrovascular, neurodegenerative diseases, alcoholism, vision impairment etc. (55).

The tests used for MHE diagnosis assess multiple cognitive areas including: working memory, inhibitory control, psychomotor speed, reaction speed and visual-motor coordination. We list below the techniques used for MHE diagnosis adapted from Dhiman et al.: Neuropsychological assessment using series of tests with proven clinical applicability, although time-consuming. Computerized tests (Critical Flicker Frequency, Inhibitory Control Test, Continuous Reaction Times) are rapid, easily applicable tests but with limited data regarding diagnostic significance and requiring standardization prior to use. Neurophysiological tests (Electroencephalography, Spectral Electroencephalography, Evoked Potentials P300) are objective, may be repeated but require sophisticated equipment in order to be applied. Short neuropsychological tests (PHES) have high sensitivity, demonstrated clinical applica-

bility with quick results but also have limited access and requirements of standardization prior to use. CDR computerized assessment battery are sensitive with rapid results but the limited access, high price and the need for training courses prior to use constitute major drawbacks for widespread usage (56). ISHEN recommends psychometric tests such as PHES, as a first-line option for the diagnosis of MHE. In the absence of prior PHES standardization, previously studied alternative tests will be used, for which normative data is available (57).

At present there is no universal test for the diagnosis of MHE, and there are controversies in the literature regarding the benefits resulting from the treatment of this pathology. Screening all cirrhotic patients for MHE is not recommended. The neurocognitive assessment should be individualized and taken into consideration especially in patients with an increased risk of accidents (labor or machine) and in those with cognitive complaints or associating alteration of the work capacity (55).

TREATMENT

Given the central role ammonia has in MHE pathogenesis, literature studies focused on investigating pharmacological agents that decrease ammonia levels. The therapies are similar to those used for the treatment of OHE: non-absorbable disaccharides (lactulose), antibiotics (rifaximin), probiotics/synbiotics and branched aminoacids (58). In clinical setting, non-absorbable disaccharides are most commonly used for the treatment of MHE (58). However, a meta-analysis of randomized trials suggests that antibiotics such as rifaximin may prove more useful (59). Recent studies have shown the benefits of lactulose and rifaximin in improving the cognitive function and the quality of life in cirrhotic patients with MHE. (60, 61, 62, 63) Given their modulating properties of the intestinal microbiome, probiotics, synbiotics and yoghurts may stand as effective, reliable and long-term solutions for the treatment of MHE. Studies to date are inconclusive because they were conducted over short periods of time and on a relatively small number of patients (64, 65).

MHE medical treatment should be individualized and requires a dynamic evaluation following objective indicators for an accurate assessment of the therapy response. Treatment is mainly targeted at patients with cognitive complaints, those associating alteration of the work capacity and drivers. (55)

CONCLUSIONS

MHE is the initial stage of the spectrum of neurocognitive impairment associated with liver cirrhosis. Despite the term "minimal", this entity is associated with reduced quality of life, socioeconomic status deterioration, reduced driving ability and faster progression to OHE.

Ammonia has a central role in MHE pathogenesis. Complementary factors such as inflammation, oxidative stress, manganese and IBO require further studies in order to determine the exact extent of their involvement in the development of MHE. Although not routinely recommended, early diagnosis and treatment in patients with MHE leads to an improvement of the cognitive deficits and increased quality of life.

EDITORIAL

THE LINK BETWEEN DIET AND CANCER

Cancer has gradually become one of the most important pathologies associated with both significant physical or psychological suffering and important financial costs that put a strain on economy. Identifying cancer risk factors is a constant goal of many epidemiological studies and recent data indicates that lifestyle is a major contributor to the general increase in cancer incidence. Currently, diet, obesity and the lack of physical exercise are believed to be responsible for at least 35% of all human cancers. In under-developed countries, a diet that lacks certain nutrients and vitamins, together with improper conditions for food storage and other discrepancies between food requirements and daily intake are the main mechanisms responsible for diet-related cancer. In developed countries, high-fat, sugary diet, food additives and obesity are believed to increase cancer risk (1, 2).

The relationship between diet and cancer risk is complex. Diet can (1) represent a source of procarcinogens or carcinogens, (2) increase carcinogen formation through transforming nitrates and nitrites (abundantly found in some types of food and/or in water) in nitrosamines, (3) modulate carcinogenic effects or (4) modify gene expression through epigenetic regulative processes.

Thermal food processing can result in carcinogenic byproducts. For instance, frying or smoking meat can lead to the formation of polycyclic aromatic hydrocarbons such as benzopyrene. Smoked meat and smoked fish consumption have been linked to gastric cancer in countries with high intake, such as Japan. Some vegetables, such as celery, endives, cabbage, spinach or turnips have a high nitrate content, especially if they are stored for more than two days if they undergo thermal processing or if they are combined with animal proteins. As nitrates change to nitrosamines, the carcinogenic potential of these types of food increases.

Most of the processes through which food is conserved can increase the risk of cancer. Both salt and salting as a conservation technique have been linked to gastric cancer. Some additives or food preservers, currently used for adding color, taste, aroma or consistency have mutagenic potential, which is why some have been withdrawn from the food processing industry. Nitrates, sometimes used as food preservers for meat, are transformed in the gastrointestinal tract into nitrites if a *Helicobacter Pylori* infection is present. Nitrites then combine with secondary amines to form nitrosamines, which is why any type of food that contains nitrates should be consumed in moderation. Also, a high saccharine intake has been linked to bladder cancer in mice. However, currently there is no evidence to link saccharine consumption and cancer risk in humans.

Diet can also act as a protection against cancer. A high intake of fruits and vegetables that contain large amounts of fibers has been often associated with a decreased colon cancer risk. Similar associations have been noted for gastric cancer and for other epithelial malignancies such as lung, phar-

ynx, larynx, esophageal and breast cancer. Consuming large amounts of food that contain phytoestrogens (selective estrogen modulators) may contribute to primary and secondary prophylaxis of endocrine-dependent cancers.

Among xenobiotics, the following associations are currently considered scientifically valid:

- a diet rich in saturated fats is associated with an increase in colon, breast, prostate and endometrial cancer;
- deep-fried meat contains polycyclic amines, linked with gastric, colon, rectal, pancreatic and breast cancers;
- diets which exceed the daily recommended caloric intake increase the risk of biliary, breast, endometrial, colon and prostate cancer;
- an excess of animal proteins, particularly from red meat, are associated with breast, colon and endometrial cancer risk;
- excessive alcohol consumption is linked with oral, pharynx, larynx, liver and esophageal cancers, especially in combination with smoking;
- a high-salt diet and smoked meat consumption is associated with esophageal and gastric cancer;
- food preservers and food additives are associated with intestinal cancer (3, 4).

Red meat intake

As previously mentioned, both red meat (beef, pork, lamb, horse) and processed meat (salami, pastrami, ham, or other types of meat preserved by means of salting, smoking, deep frying or adding food preservers) increase the risk for pancreatic, colon, rectal, breast, kidney and prostate cancer. Eating red meat more than one time per week increases colon and rectal cancer risk by approximately 40%, whereas each additional 50g/day of processed meat increases cancer risk by 20%.

One of the most popular theories that explains the relationship between red meat intake and cancer risk is that red meat has a high hemoglobin content which irritates the colon and rectal mucosa and leads to an electrophilic aggression that initiates carcinogenesis. One other mechanism is the transformation of red meat amino acids in aggressive intermediate compounds that react with nitrates and nitrites in the bowel, a chemical reaction catalyzed by the hem from hemoglobin. The recommended amount of red meat intake is 500 g/week (a maximum of 5 meat servings/week). Also, current healthy eating guidelines advice against eating meat prepared by means of deep frying.

Vegetable products

Most types of food believed to protect against cancer have vegetable origin. Starch-free vegetables protect against upper gastro-intestinal cancers: oral cancers, pharynx, larynx, epidermoid esophageal cancers, gastric adenocarcinomas, colon and rectal cancers, pancreatic, breast and bladder cancer. A high fruit intake protects against oral and pharynx cancers, esophageal, lung, colon and rectal cancers. There is some evidence suggesting that garlic intake protects against colon and rectal cancers and a high tomato intake protects against prostate cancer (most likely due to the high amount of lycopene found in tomatoes).

The protective effect against cancer found for both fruits and vegetables is most likely due to a high content of vegetable

fibers, specific vitamins and certain bioactive compounds such as carotene (found in "red vegetables"), folates (found in "green vegetables"), glycosylates (brassica) and alkyl sulfates (garlic).

Current guidelines recommend a daily vegetable intake of 600-800 g/day and eating at least two fruits to decrease breast, colon, rectal and pancreatic cancer risk. Of these, at least 400 g/day (preferably divided into five portions) should consist in starch-free vegetables, fruits or unprocessed seeds (6). Some additional information regarding the choice of fruits and vegetables:

- the highest number of antioxidants can be found in strawberries, raspberries, blackberries and wild berries ("small red fruits");
- vitamins C, E and A, together with Q coenzyme, lycopene, melatonin, quercetin, Selenium and Zinc represent natural antioxidants;
- vitamin C has a strong antioxidant and anticancer effect and can be found in several types of fruits such as: blackberries, cranberries, broccoli or red cabbage. Because most of the vitamins are photosensitive, fruits should be stored in a dark dry place;
- vitamin A is found as β-carotene in: carrots, spinach, broccoli and green cabbage. Heavy smokers (more than one pack of cigarettes/day) should avoid vitamin A supplements because they have been linked with an increase in lung cancer incidence for this population group;
- vitamin E can be found together with unsaturated fatty acids in eggs, meat, fish, cereals, seeds, nuts and soy. Some studies have linked a high vitamin E intake with a protective effect against prostate cancer;
- starch-free vegetables have a low caloric count and a diet rich in these vegetables also protects against gain weight.

Other types of food and cancer risk

Phosphoric calcium may reduce colon cancer risk through its ability to bind biliary acids and free fatty acids, thus blocking their effects on the gastro-intestinal tube.

A high milk intake could increase prostate cancer risk through increasing blood Calcium levels and insulin-growth factor 1 (IGF-1) (5, 6). High Calcium levels inhibit 1,25-dihydroxyvitamin D formation, which could in turn stimulate prostate cell proliferation.

Omega-3 unsaturated fatty acids that are found in high concentrations in fish oil protect against several types of cancer and exhibit cardiovascular protective effects. However, there is one study that linked a high fatty acid intake to prostate cancer.

Obesity

After reviewing all epidemiological studies performed in the past thirty years, the *International Agency for Research on Cancer* (IARC) has recently determined that obesity is an important risk factor for several types of cancer. Obesity is responsible for the death of one in seven males and one in five females in the United States and accounts for 4% of male cancers and 7% of female cancers in the European Union. The link between cancer and obesity is quite complex (1, 3). Each five-kilogram weight gain is associated with a 1.08 increase in breast cancer in menopausal women. Each one-unit increase in the Body Mass Index increases breast cancer risk by 3%. In the United States, obesity is responsible for 20% of all breast cancers in men-

opausal women and 50% of all breast cancer-related deaths in this population group.

Being overweight is one of the most important risk factors for several types of cancers such as: colon cancer, breast cancer (in menopausal women), endometrium cancer, esophageal adeno-carcinoma, pancreatic and kidney cancer and, to a certain extent, biliary cancer (4).

Some more information regarding obesity-related cancers:

a) endometrial cancer risk in women with a more than twenty-kilogram weight gain after the age of eighteen is five times higher than in the normal population;
b) colon cancer incidence is significantly higher in both men and women that are obese;
c) obesity increases likelihood of kidney cancer especially in women, although the exact mechanism is not yet understood;
d) esophageal cancer: obese individuals have a higher incidence of gastro-esophageal reflux disease (GERD), which is associated with Barret's esophagus, a precursor metaplastic lesion. People with Barret's esophagus have a higher risk for esophageal adenocarcinoma. However, some studies indicate that the link between esophageal cancer and obesity is independent of GERD;
e) other cancers for which the link with obesity is not yet fully certified: pancreatic cancer (risk is increased 2x for obese individuals), hepatic caner, cancer of the cardia (most likely due to Barret metaplasia), ovarian and cervical cancer (limited data) and lymphoma. Additional epidemiological studies are required to firmly link these cancers to obesity.

METABOLIC SYNDROME A WIDESPREAD THREATENING CONDITION; RISK FACTORS, DIAGNOSTIC CRITERIA, THERAPEUTIC OPTIONS, PREVENTION AND CONTROVERSIES: AN OVERVIEW (Abstract): Metabolic syndrome diagnostic criteria include at least three of five of the following medical conditions: abdominal obesity, high blood pressure, abnormal high fasting plasma glucose, elevated serum triglycerides and low HDL (high – density cholesterol) level. Sedentary, overweight and obesity are characteristically associated with the syndrome, nevertheless there are new studies which indicate that chronic stress, through deregulation of the hypothalamic-pituitary-adrenal (HPA) axis is also involved in the development of the syndrome. Metabolic syndrome represents a significant risk for the development of the cardiovascular diseases. New studies in the USA have estimated its prevalence at approximately 34 % of the adult population and its prevalence is increasing with age. Diagnosis guidelines are establishing the metabolic syndrome diagnostic when are met three of the following five conditions: fasting glucose ≥ 100 mg/dL or type 2 diabetes receiving drug therapy for hyperglycemia; high blood pressure ≥ 130/85 mm Hg or high blood pressure receiving drug therapy; triglycerides ≥ 150 mg/dL or treatment for plasma hyper-triglyceride value; HDL-C < 40 mg/dL in men and < 50 mg/dL in women or if under therapy for reduced HDL-C levels and waist circumference of ≥ 102 cm in men and ≥ 88 cm in women. Besides important change of lifestyle, often drug therapy is needed (diuretics and ACE inhibitors, cholesterol drugs and weight loss medications). The value of physical activity and diet in prevention and treatment of the syndrome is supported by numerous studies. Association of metabolic syndrome and cardiovascular risk is still a matter of controversy, in what concerns the lack of significant cardiovascular risk in the case of obesity itself without metabolic syndrome. **Keywords**: METABOLIC SYNDROME, OBESITY, HPA (HYPOTHALAMIC-PITUITARY-ADRENAL) AXIS, HDL CHOLESTEROL, LDL CHOLESTEROL

Metabolic syndrome is a disorder affecting the energy use and storage. Criteria needed for diagnosis are including at least five of the following medical conditions: abdominal obesity, high blood pressure, abnormal high fasting plasma glucose, elevated serum triglycerides and low HDL (high density cholesterol) level. Metabolic syndrome represents a significant risk for the development of cardiovascular diseases and diabetes. Different studies have estimated the prevalence of the syndrome in the USA at approximately 34 % of the adult population (1, 2).

Metabolic syndrome is also known as: insulin resistance syndrome, syndrome x, metabolic syndrome x, cardio metabolic syndrome. The term of metabolic syndrome was first used in the late 1950 s and became commonly used at the end of 1970 s, first to describe association of risk factors for diabetes (3). In 1947 it was first noticed that the upper body obesity was predisposing to diabetes, atherosclerosis and gout. In 1977 was used the term of metabolic syndrome to describe the association between obesity, diabetes mellitus, hyper-lipoproteinemia, hyperuricemia and hepatic steatosis and thus to contour the risk factors for atherosclerosis (2, 4).

RISK FACTORS

New researches are indicating that chronic stress is involved in the development of the metabolic syndrome, by disruption of the hormonal balance of the hypothalamic-pituitary-adrenal axis (HPA-axis). Disruption of HPA-axis induces increased circulatory cortisol levels with consequently high glucose and insulin levels, finally leading to insulin-triggered effects on adipose tissue and resulting into visceral adiposity, insulin resistance, dyslipidemia, high blood pressure and effects on bone metabolism, with the development of "low turnover" osteoporosis. Disruption in the functioning of HPA-axis is explaining the involvement of the abdominal obesity in the development of the cardiovascular disease, type 2 -diabetes and stroke (5).

Overweight and obesity is the main characteristic of the syndrome, reflected in the strong link between its prevalence and waist circumference, associated with increasing adipose mass. Nevertheless, there are cases which show normal weight but do have the syndrome (6). Sedentary behavior is one of the main risk factors for cardiovascular diseases and mortality. Most of the metabolic syndrome's features are associated with sedentarism: increased abdominal adipose tissue, low HDL cholesterol level, high blood pressure, high glucose levels (7).

Metabolic syndrome affects 44 % of the US population over 50 years of age. The syndrome is more frequent in female sex and its prevalence is increasing with age, all over the world. Metabolic syndrome is increasing five folds the risk of type 2 diabetes mellitus, which is seen like a complication of the syndrome. It is believed that pre diabetes and metabolic syndrome are representing in fact the same disorder, but defined by different sets of biological markers. Metabolic syndrome is associated with a higher risk for cardiovascular disease, than the cases with type 2 diabetes mellitus without associated metabolic syndrome. Hypoadiponectinemia is increasing insulin resistance and it represents also a risk factor for the development of the metabolic syndrome.

Patients with schizophrenia and other psychiatric diseases are at high risk for metabolic syndrome, a risk which is increased in such cases by sedentary behavior, noxious dietary habits and antipsychotic drug – induced adverse effects. 32 to 51 % of individuals with psychiatric disorders have metabolic syndrome, with a higher prevalence in women than in men (2, 8). Common triggers, such as excessive sugar intake and generally overabundant food environment are incriminated in the concomitant development of multiple metabolic abnormalities at the same time, pointing once more the dysfunction of energy use and storage paths in the metabolic syndrome (8, 9, 10).

Markers of systemic inflammation, such as C-reactive protein, fibrinogen, interleukin 6, tumor necrosis factor alpha (TNF-α) are increased in the metabolic syndrome. TNF-α is causing the production of inflammatory cytokines and is inducing cell signaling through interaction with TNF-α receptor, which may lead to insulin resistance. Increase of adipose tissue is increasing the number of immune cells inside it, cells which are involved in the chronic inflammatory processes; chronic inflammation being a risk factor for the development of arterial hypertension, atherosclerosis and diabetes (11).

DIAGNOSTIC CRITERIA

Main symptom of metabolic syndrome is the central obesity (also-known as visceral, male-pattern or apple-shaped adiposity) – an overweight with accumulation of adipose tissue mainly around the waist and trunk (6). Signs of metabolic syndrome include: high blood pressure, decreased fasting serum HDL cholesterol, elevated fasting serum triglyceride level (VLDL triglyceride), impaired fasting-glucose level and insulin resistance. Metabolic syndrome is usually associated with hyperuricemia, hepatic steatosis, polycystic ovarian syndrome in women and erectile dysfunction in men, and acanthosis nigricans, xanthomas or xanthelasmas, in patients with severe dyslipidemia (12).

The diagnosis guidelines from National Heart, Lung and Blood Institute (NHLBI) and the American Heart Association (AHA) are stipulating that the diagnosis of metabolic syndrome is established, when are met three of the following five conditions (13):

- fasting glucose ≥ 100 mg/dL or type 2 diabetes which is receiving drug therapy for hyperglycemia;
- blood pressure ≥ 130/85 mmHg or high blood pressure which is under drug therapy;
- triglycerides ≥ 150 mg/dL or if treated for hypertriglyceridemia;
- HDL-cholesterol < 40 mg/dL in men and < 50 mg/dL in women, or if under therapy for reduced HDL-cholesterol;
- waist circumference ≥ 102 cm in men, or ≥ 88 cm in women.

Complaints of chest pain, dyspnea or claudication are frequent symptoms of potential complications. Obstructive sleep apnea seems to be a novel risk factor for metabolic syndrome (14).

A matter of controversy is represented by the fact that adipose tissue and resulted obesity are generally explaining most of the cardiovascular risk. Nevertheless, obesity itself, without metabolic syndrome is not associated with a significant cardiovascular risk, while metabolic syndrome without obesity is associated with a significant risk of cardiovascular disease and diabetes.

Generalized lipodistrophy characterized by an almost complete absence of adipose tissue develops signs of metabolic syndrome in the absence of adipose tissue, resulting in type 2 diabetes. Type 2 diabetes is cured if in transgenic mice with lipodistrophy, adipose tissue is transplanted (15, 16).

THERAPEUTIC OPTIONS AND PREVENTION

Change of lifestyle is the first choice treatment of the metabolic syndrome. If the efforts of reversing the risk factors are not giving expected results in 3 to 6 months, then drug therapy is needed. Diuretics and ACE inhibitors are used to treat arterial hypertension. Cholesterol drugs are used to

reduce LDL cholesterol and triglycerides elevated levels and to increase HDL low levels. Sometimes are used weight loss medications, which may result in weight loss.

As obesity is generally considered the main feature of the syndrome which is leading to the development of the other symptoms, weight loss as well as lifestyle changes, including diet and physical activity, may reduce the need for medications. Many studies are supporting the value of physical activity and diet in the therapy of the metabolic syndrome. Restriction of the total dietary carbohydrate intake shows most efficiency in decreasing common manifestations of the metabolic syndrome. Unfortunately, high-dose statins therapy has been resulted in rapid progression to diabetes (17).

Different strategies are used to prevent the development of the metabolic syndrome, like increased physical activity (for example walking 30 minutes daily) and low caloric diet. International Obesity Task force is supporting the idea of a need for sociopolitical measures to decrease the rate of metabolic syndrome development in population. Caerphilly Heart Disease Study which followed 2375 male subjects over 20 years suggested that daily intake of approximately 568 ml of milk or correspondent dairy derivatives reduced with more than 50 % the risk of metabolic syndrome. There are studies which support these findings, while others are questioning them (7, 18, 19).

ONCOPLASTIC MAMMOPLASTY ASSOCIATED WITH POSTMASTECTOMY RADIATION THERAPY: THE PLAN FOR REDUCING RECONSTRUCTIVE COMPLICATIONS

It is widely accepted that breast cancer patients who require radiation therapy after mastectomy and immediate reconstruction treatment, suffer high complication rates. A group of researchers from University of California showed that combining neo-adjuvant chemotherapy with oncoplastic mammoplasty is one of the best solutions for high aesthetics results with low local recurrence rates for patients needing radiotherapy treatment after surgery. 64 patients mastectomized with immediate reconstruction were compared with 37 who underwent the new procedure. After using the Fisher's exact test, the results showed rates of complications for infection 16.2% *versus* 35.9% ($p < 0.04$), for skin flap necrosis 10.8% versus 29.7% ($p < 0.05$) and for unplanned intervention 2.7% versus 37.5% ($p < 0.001$), much higher for the mastectomy group (excepting seroma – 7.8% versus 5.4%, $p = 0.6$). The authors show that oncoplastic mammoplasty is highly recommended to patients with local tumor in advanced stages, in order to avoid complications of multiple long lasting surgical procedures, improving quality of our patients' life. (Peled AW, Sbitany H, Foster RD, Esserman LJ. Oncoplastic mammoplasty as a strategy for reducing reconstructive complications associated with postmastectomy radiation therapy. *Breast J* 2014; 20(3):302-7)

NO COLORECTAL CANCER SCREENING PROGRAM IN ROMANIA! THUS, START WITH OPPORTUNISTIC SCREENING (Abstract). Colorectal cancer is a major health problem in the world. It can be detected in asymptomatic early stages so screening programs have been implemented in many countries for many years. Unfortunately, in Romania, the screening program for the detection of colonic pathologies is still not working. This paper suggests that an opportunistic colorectal cancer screening may be a solution in our country. This means that when a physician is contacted by a subject older than 50 years, a colorectal screening procedure – fecal occult blood testing or colonoscopy should be suggested to him/her. Thus, by collaborating between physicians from many specialties (gastroenterologists, general practitioners, internal medicine specialists, and surgeons) we hope to decrease the rate of advanced colorectal cancers found in daily practice. **Key words:** COLORECTAL CANCER SCREENING, COLONOSCOPY, FECAL OCCULT BLOOD TESTING.

Colorectal cancer is an important oncologic problem both in Europe and in the world. Even if it is in the top three human cancers, it has the advantage that it can be detected in asymptomatic early stages, by screening programs. On the other hand, progression from adenomatous polyps to cancer is a known and documented fact. Thus, by performing polypectomies, we can decrease the rate of colon cancer.

This is why screening programs for the detection of asymptomatic colorectal cancers and of colonic polyps were implemented in many countries, years ago.

Several studies proved that colorectal cancer screening programs decreased the mortality by colonic cancers (1-3), regardless of the screening strategy (based on fecal occult blood testing – such as FOBT or FIT - or on colonoscopy).

Many years ago, in Romania it was decided that colorectal cancer screening programs are valuable and a pilot study was started. Unfortunately, even after 10 years, the screening program for the detection of colonic pathologies is still not working.

A legislative program for cancer screening in three organs was issued some years ago: for breast, cervix and colon cancer. But no financial support was provided for the colorectal cancer screening during the last years!

Efforts were made by the National Society of Gastroenterology and Hepatology (SRGH) to obtain funding for this program, but nothing happened!

Thus, what to do? There is not time to wait since in every day practice, the endoscopists find too many advanced colorectal cancers (sometimes with metastases).

Of course, it is a priority to continue the pressure on politicians to find financial support for such a program, but this is not enough!

Can we find other available methods?

We believe that we must start with an opportunistic colorectal cancer screening.

What does this mean?

It means that when a physician is contacted by a subject older than 50 years, a colorectal screening procedure should be suggested to him/her.

These colorectal screening procedures can be performed according to the financial means of patients or according to the physician's preference (fecal occult blood tests are very cheap and can be preferred by general practitioners - GP, while colonoscopy may be preferred by gastroenterologists, internal medicine specialists or surgeons).

In a recent study (4) performed in Romania in a large cohort of asymptomatic subjects (2433 patients), using colonoscopy as screening method for colonic pre neoplasic and neoplasic lesions, we found in polyps in 32.1% of cases (in 7.2% cases polyps larger than 1 cm) and carcinomas in 2% of cases. What does this mean? By adding cancers and large polyps, in 9.2% of cases we found an advanced disease (1/11 asymptomatic subjects have pre neoplastic or neoplasic lesions).

Thus, using this modality of screening that can be offered to all patients over 50 that contact a physician, we can discover a lot of pathological cases in early stages.

In addition we can decrease the risk for further cancers by performing polypectomy for all detected polyps.

Gastroenterologists play a major role in the awareness of colorectal cancer risk. We must train the other specialists regarding this risk and we should work together for the opportunistic screening (at least until a population based screening program will properly funded).

The GPs must know the real value of fecal occult blood tests (and which is the difference between FOBT and FIT), how often to propose these tests to the patients (annually or biennial), or if they should propose a colonoscopic evaluation (with the advantage that a normal colonoscopy must be repeated only after 10 years).

On the other hand, all must be informed regarding the importance of colonoscopy's quality (cecal intubation in more than 90-95% of cases); of the preparation for colonoscopy; regarding which is the risk for complications and on other issues on this topic.

Of course, we can talk about the funding of a screening program. Usually this is covered by the National Health Authority!

But since this is still not happening in Romania, we must do something. And the only thing that we can do (excepting political pressure) is to work in the patients' interest, with the opportunistic screening.

Thus, by collaborating with physicians from other specialties: GPs, internal medicine specialists, surgeons and maybe others, we can decrease the rate of advanced colorectal cancers found in daily practice.

Thus, don't worry..... begin the opportunistic screening stating from tomorrow, so we can fulfill our task of decreasing the number of advanced cases.

BETA-BLOCKER MEDICATIONS AND RISK OF PSORIASIS

Psoriasis is an immune-mediated skin disease which can affect internal organ such as cardiovascular system. Besides, cardiovascular diseases have been linked to psoriasis development. In a study published in *JAMA Dermatology*, the authors evaluated the association on hypertension and beta (β)-blocker medication with risk of psoriasis. The study group included 77 728 normotensive and hypertensive women, with or without antihypertensive medications. The results showed that the hypertensive women with long-term status (6 years or more) have had a higher risk of developing psoriasis compared with normotensive women. Also, the highest risk of psoriasis was documented among hypertensive women who used β-blockers for 6 years or more. These results sustain the role of hypertension and medications in psoriasis development. (Shaowei Wu, Jiali Han, Wen-Qing Li et al. Hypertension, antihypertensive medication use, and risk of psoriasis. *JAMA Dermatology*, 2014; DOI: 10.1001/jamadermatol.2013.9957).

A NOVEL TRANSUNGUAL PERMEATION ENHANCER FOR TOPICAL DRUG DELIVERY SYSTEM IN ONYCHOMYCOSIS

The treatment of onychomycosis is difficult because of the barrier properties of the nail plate that impede the passage of antifungal drugs. In a study by Chouhan et al., hydroxypropyl-β-cyclodextrin (HP-β-CD) was tested as a transungual drug permeation enhancer for poorly water soluble antifungal drugs such as terbinafine hydrochloride. According to Chouhan et al., HP-β-CD improves hydration of nail plates and increases solubility of terbinafine hydrochloride. Using HP-β-CD as a permeation enhancer, the researchers designed a nail lacquer formulation (containing 10%w/v of HP-β-CD) to deliver the drug in an effective concentration across nail plates, proving *in vitro* higher flux ($4.586 \pm 0.08 \mu g/mL/cm^2$) than the control formulation ($0.868 \pm 0.06 \mu g/mL/cm^2$). The study concluded that HP-β-CD is an effective permeation enhancer for transungual delivery of terbinafine hydrochloride and other poorly water soluble drugs (Chouhan P, Saini TR. Hydroxypropyl- β -cyclodextrin: a novel transungual permeation enhancer for development of topical drug delivery system for onychomycosis. *J Drug Deliv*. 2014;2014:950358. doi: 10.1155/2014/950358).

CARDIAC TUMORS (Abstract): Cardiac tumors are a group of rare disorders with a frequency that varies in population studies between 0.0017% and 0.33%. There are primary cardiac tumors with an incidence of 5% of all cardiac tumors and secondary tumors (metastases of the heart) in 95% of cases. Symptoms are nonspecific and can mimic many other heart diseases. This fact makes the diagnosis of cardiac tumors very difficult. Approximately 75% of the primary cardiac tumors are benign; the most frequent histological type encountered is myxoma in 50 % of cases, followed by cardiac fibromas, lipomas, rhabdomyomas, hemangiomas, teratomas, papillary fibroelastomas, pericardial cysts or cystic tumor of the atrioventricular node region. Secondary cardiac tumors (metastases) are 20 times more common than primary cardiac tumors. Paraclinical methods (especially imaging evaluation) are always necessary for the complete diagnosis: transthoracic and transesophageal echocardiograms are the gold standard investigations in the diagnosis of the cardiac tumors; CT scans together with MRIs are complementary diagnostic methods that are useful when the diagnosis is uncertain. In the majority of cases surgical treatment is recommended. **Keywords:** CARDIAC TUMOR, MYXOMA, ECHOCARDIOGRAPHY.

Cardiac tumors are a group of rare disorders with a frequency that varies in population studies between 0.0017% and 0.33% (1). There are primary cardiac tumors with an incidence of 5% of all cardiac tumors and secondary tumors (metastases of the heart) in 95% of cases (2). The diagnosis of primary cardiac tumors is frequently a challenge. Symptoms associated with most of them are nonspecific and can mimic many other heart diseases. Therefore, the diagnosis of cardiac tumors is difficult to be made when the first signs appear.

Classification

Approximately 75% of the primary cardiac tumors are benign; the most frequent histological type encountered is myxoma, in 50 % of cases. There can also be cardiac fibromas, lipomas, rhabdomyomas, hemangiomas, teratomas, papillary fibroelastomas, pericardial cysts or cystic tumors of the atrioventricular node region (2).

The remaining 25% are malignant tumors most frequently represented by sarcomas (angiosarcomas, fibrosarcomas, liposarcomas, leiomyosarcomas, osteosarcomas), lymphomas and mesotheliomas (2, 3).

Paragangliomas and pheochromocytomas can also be, depending on their anatomopathological characteristics, benign or malignant cardiac tumors (4).

Secondary cardiac tumors (metastases) are 20 times more common than primary cardiac tumors. In various necropsy studies in patients with malignant diseases, the heart is affected in 10% of cases (5). Cardiac metastases can occur by: direct invasion: lung cancer, breast cancer; hematogenous: melanoma, sarcoma; lymphatic extension: epithelial carcinoma.

Pathophysiology

Pathophysiological changes caused by cardiac tumors depend on: nature of the tumor (benign *vs.* malignant), localization, histological type, embolic potential and secretor or non-secretor character of the tumor.

Primary cardiac tumors in adults most commonly develop in the subendocardial tissue, rarely at the pericardial or myocardial level. Cardiac metastases frequently locate in the pericardium (epithelial neoplasms). Tumors that develop from the big blood vessels can metastasize in the endocardium (4, 5).

There are some preferential localizations of the cardiac tumors (5):

- Left atrium: myxoma and myxomatous hypertrophy of the interatrial septum;
- Right atrium: angiosarcomas;
- Left ventricle: fibromas, rhabdomyomas;
- Ventricular septum: angiomas;
- Valves of the heart: papillary fibroelastomas.

Clinical signs

Signs and symptoms related to cardiac Tumors can be very different; therefore the diagnosis might be considerably delayed. They depend primarily on the localization of the tumor and the anatomopathological characteristics.

Patients can be completely asymptomatic or may present:

- Signs of right or left heart failure: dyspnoea, oedema of the legs, fatigue; they can also present acute pulmonary oedema and low cardiac output syndrome;
- Supraventricular (atrial fibrillation or flutter) and ventricular arrhythmia;
- Atrioventricular blocks;
- Signs of valvular disease;
- Pericardial effusion;
- Pulmonary or systemic thromboembolism;
- Signs and symptoms that most frequently occur in malignant Tumors: fever, weight loss, impaired general condition, immunological signs: arthralgia and Raynaud's phenomenon (4).

Cardiac tumors can mimic a variety of other cardiac and non-cardiac pathology. Right atrial tumors can mimic Ebstein disease, constrictive pericarditis or atrial septal defect; left atrium tumors may be confused with mitral valvular heart disease or endocarditis; the right ventricle Tumors with pulmonary stenosis or pulmonary embolism and the left ventricle Tumors with aortic valvular disease or obstructive hypertrophic cardiomyopathy (4).

Paraclinical signs

Paraclinical, hematological and biochemical changes and the imaging evaluations are essential for assessing the surgical risk and patients' follow-up.

Hematological and biochemical changes include: signs of inflammation (increase in erythrocytes sedimentation rate, C reactive

protein and fibrinogen), presence of anaemia or polyglobulia, thrombocytosis, thrombocytopenia or leukocytosis. Protein alterations may also occur through the increase in gamma globulins (4).

The electrocardiogram is nonspecific most of the times. The patient usually has a sinus rhythm. The existence of a large left atrial myxoma can lead to atrial fibrillation. Atrioventricular blocks can also occur. Ischemic changes or necrosis can occur when tumor fragments embolise at the level of the coronary arteries.

Thoracic radiography can be normal. Cardiomegaly, cardiac calcifications or pericarditis can indicate the existence of a cardiac tumor formation.

Transthoracic and transesophageal echocardiograms are the gold standard investigations in the diagnosis of the cardiac tumors. They have a sensitivity of 93%, 97% respectively (4, 5). They are a non-invasive diagnosis method that offers a multitude of morphological and functional information about the tumor. They can identify the tumor localization and size, the existence of vascularisation, as well as the impact it has on the heart function. The transesophageal echocardiogram offers a better imaging of the atria and the interatrial septum. It provides a higher resolution imaging of the tumor and it can detect such growths that are not visible in a transthoracic echocardiogram. It provides a better visualization of the right atrium Tumors (2).

CT scans together with MRIs are complementary diagnostic methods that are useful when the diagnosis is uncertain. The CT scan is a useful investigation for assessing the degree of intramural, pericardium and extracardiac damage. The MRI provides good accuracy in the 3D scans of the tumors and in their differentiation from other intracardiac formations (5).

Cardiac catheterization and angiography are not indicated as routine investigations due to the high risk of peripheral embolisation through the dislocation of a tumor fragment or an associated thrombus. They are reserved for the cases where the visualization of the tumor is difficult using the non-invasive diagnosis methods and in the case of other associated cardiac diseases. The situation is different in the case of vascularised tumors where the cardiac catheterization and coronarography can be used to identify the coronary artery that provides the vascularisation of the tumor (4).

Treatment

Cardiac tumors treatment is influenced by the histological type of the tumor. In the case of benign cardiac tumors, the treatment primarily includes surgery for tumor excision. This depends on its type and on patient's symptomatology. In the case of the symptomatic patients the complete excision of the tumor leads to their healing.

In the case of cardiac myxomas, surgery is recommended to be done as soon as possible, even if the patient is symptomatic or not, due to the high risk of embolism through the breaking of small tumor fragments. Surgery involves the complete excision of the tumor together with the pedicle or/and the insertion area (*fossa ovalis*) plus 5 mm of surrounding normal endomyocardial tissue in order to avoid recurrences (5). The relapse risk is also high in the case of cardiac fibromas, hemangiomas and lymphomas.

Similarly, the decision for surgery has to be prompt in the case of a mobile papillary fibroelastoma of over one cm.

On the contrary, in patients diagnosed with cardiac lipomas or lipomatous hyper-

trophy of the atrial septum the surgery should be indicated only for those who show significant hemodynamic disorders.

The treatment for malignant tumors is similar to the cases in which these anatomopathological subtypes are located in other places in the body. Although surgery offers the chance of a curative treatment, this is in many cases a difficult target to hit due to early metastases.

Most treatments are palliative and are done in order to remove the cardiac obstruction, improving the heart functions for a limited period of time. Chemotherapy can help in certain cases by reducing the mass of the tumor and facilitating the excision.

Sarcomas benefit from surgical treatment with curative effect in the case of small tumors without secondary dissemination. Cardiac angiosarcomas require a multidisciplinary approach that includes surgery, chemo radiotherapy and immunotherapy (6).

The inoperable cardiac sarcomas or the ones with metastasis at the moment of diagnosis mainly benefit from chemotherapy.

Despite the use of these multiple therapies, the average survival of the patients diagnosed with cardiac sarcoma is of one year at the most (6).

Cardiac lymphomas are generally sensitive to chemotherapy. Prompt chemotherapy with or without adjuvant radiotherapy became the elective treatment of these tumors. Surgical excision remains the second principle of treatment that can be approached (6, 7).

Usually, the treatment of secondary cardiac tumors is palliative and symptomatic. Surgery procedures, chemo and radiotherapy can be used.

CONCLUSIONS

Cardiac tumors are a group of rare disorders that, due to the physiopathological changes, lead to the increase of mortality in the absence of an efficient treatment. The diagnosis and treatment of primary cardiac tumors will always be a challenge for doctors and surgeons due to their rare occurrence as pathology and the lack of a predefined guide for their management. However, taking cardiac tumors into account within the differential diagnosis together with a high suspicion index are essential in making a correct diagnosis.

A REVIEW ON THE CAUSE-EFFECT RELATIONSHIP BETWEEN OXIDATIVE STRESS AND TOXIC PROTEINS IN THE PATHOGENESIS OF NEURODEGENERATIVE DISEASES

Liana Rada Borza

Faculty of Medicine
Clinical Hospital of Psychiatry "Socola" – Iaşi

A REVIEW ON THE CAUSE-EFFECT RELATIONSHIP BETWEEN OXIDATIVE STRESS AND TOXIC PROTEINS IN THE PATHOGENESIS OF NEURODEGENERATIVE DISEASES (Abstract): Protein aggregates are the defining pathological feature of human neurodegenerative diseases. Studies have revealed that mutant huntingtin, polyglutamine-expanded ataxin-1 and ataxin-3 can cause elevated levels of reactive oxygen species in neuronal cells. It has also been indicated that the normal host prion protein behaves as an antioxidant, while the neurotoxic peptide based on the sequence of the scrapie isoform increases hydrogen peroxide toxicity in neuronal cultures. Additionally, not only can oxidative stress contribute to the aggregation of β-amyloid and α-synuclein, but both β-amyloid and α-synuclein can induce oxidative damage. Furthermore, oxidative stressors have been shown to play a critical role in neurofibrillary pathology leading to tau hyperphosphorylation. In conclusion, the present review supports a cause-effect relationship between oxidative stress and toxic proteins in the pathogenesis of neurodegenerative disorders. Keywords: NEURODEGENERATIVE DISEASES, PROTEIN MISFOLDING, OXIDATIVE STRESS

Neurodegenerative disorders as diverse as Parkinson's disease, prion diseases, polyglutamine diseases, Alzheimer's disease and related tauopathies share a common feature – aggregation and deposition of abnormal protein. Expression of mutant proteins in transgenic animal models recapitulates features of these diseases. Neurons are particularly vulnerable to the toxic effects of mutant or misfolded proteins. When they accumulate in sufficient quantity, misfolded proteins are prone to aggregation. Failure to detect and eliminate misfolded proteins contributes to the pathogenesis of neurodegenerative disease (1).

As previously mentioned, the common mechanistic theme of these diseases is the formation of aggregates containing misfolded proteins with a concomitant gain of function which eventually leads to neuronal death. A gain of function, rather than a loss of function, is sustained by the observation that the aggregates are toxic *per se*. Several studies have addressed the following question: what makes the aggregates toxic? In this regard, a widely invoked cause of membrane damage has been free radical oxidative stress (2). The oxidative damage induced by the redox activity of a target protein, which interacts with free radicals and metal ions, has been found as a typical hallmark in the majority of neurodegenerative

disorders. Thus, protein aggregation and oxidative stress have been demonstrated to be the major factors involved in the neurodegenerative process (3).

The objective of the current review would be to examine a possible cause-effect relationship between oxidative stress and the toxic proteins in the pathogenesis of neurodegenerative diseases.

POLYGLUTAMINE DISEASES

Huntington's disease (HD) is an autosomal dominant neurodegenerative disease caused by an expansion of cytosine-adenine-guanine (CAG) repeats located in the coding region of the IT15 – interesting transcript 15 – gene on chromosome 4, whose product is named huntingtin (htt) (4). In addition, intranuclear inclusion bodies have been found in the striatal neurons of transgenic mice expressing the CAG repeat containing exon 1 of the htt gene (5). The expanded polyglutamine (polyQ) tract contained by the encoded protein htt may be toxic directly and/or through interactions with other cellular proteins (6).

The interaction between the mutated N-terminal part of htt and the glycolysis enzyme glyceraldehyde-3-phosphate dehydrogenase (GAPDH) supports a role for oxidative damage in the disease process, as it impairs the glycolitic activity of this enzyme. The use of spectrophotometric assays in postmortem brain tissue has revealed impaired oxidative phosphorylation enzyme activity restricted to the basal ganglia in HD brain (7). GADPH interaction with htt has been further increased by the presence of the expanded polyQ stretch (8).

It has been observed that mutant htt (mhtt) causes increased levels of reactive oxygen species (ROS) in neuronal SK-N-SH (human neuroblastoma) cells and non-neuronal COS-7 (monkey kidney) cells. Thus, it has been postulated that endogenous heat shock protein 27 (HSP27) in its unphosphorylated form suppresses polyQ-mediated cell death by protecting against ROS induced by mhtt. It has been shown that HSP27 mutants showing protection in the polyQ model increase survival of HeLa cells exposed to hydrogen peroxide (H_2O_2). Oxidative stress is likely to be relevant to polyQ-induced death, since both N-acetyl-L-cysteine and the reduced form of glutathione (GSH) have inhibited polyQ-mediated cell death. Furthermore, cells expressing mhtt have presented decreased levels of GSH, which have been increased by co-expression of HSP27 (9).

A consequence of the defect in energy metabolism caused by mhtt may be an increase in oxidative injury, a regionally specific mechanism of neuronal death in HD. A well-established marker of oxidative damage to deoxyribonucleic acid **(**DNA) is 8-hydroxy-2-deoxyguanosine (OH8dG), and a significant increase in OH8dG in nuclear DNA has been found in the caudate nucleus in HD post-mortem tissue (7). A significant increase in OH8dG has also been found in mitochondrial DNA of parietal cortex from HD patients (10).

In addition, lipid peroxidation (LP), induced by the formation of free radicals, has been determined in the striatum, cortex and cerebellum of R6/1 transgenic mice that express a human mutated htt exon 1, with approximately 116 CAG repeats, and wild-type (WT) control mice at 11, 19, 24 and 35 weeks of age. A tendency of elevated levels of LP in the R6/1 mice has started by 19 weeks and has become significant by 24 weeks; at 35 weeks, LP in transgenic striatum was 274% higher than in non-transgenic mice. As a result, mutated htt specifically

induces progressive oxidative damage to the striatum of transgenic mice (11).

Spinocerebellar ataxia 1 (SCA1) is an autosomal dominant neurodegenerative disorder caused by the expansion of CAG trinucleotide repeats encoding the polyQ tract in ataxin-1, the SCA1 gene product. PolyQ expansion leads to the aggregation of ataxin-1 proteins in the nucleus. It has been shown that the large aggregates formed by polyQ-expanded ataxin-1 recruit the Cu/Zn-binding isoform of superoxide dismutase, SOD1, in the nucleus of HeLa cells. In the case of mutant ataxin-1-expressing cells, most of SOD1 has been detected in nuclear aggregates; in the case of normal ataxin-1-expressing cells, some Cu/Zn-SOD has been found co-localized in ataxin-1 aggregates and some diffused in the cytosol. In addition, it has been revealed that the oxidation of intracellular proteins occurs with a higher frequency in the presence of mutant ataxin-1 relative to normal ataxin-1. When treated with both BSO (an inhibitor of γ-glutamylcysteinyl synthetase, the first enzyme in the GSH biosynthetic pathway) and t-butylhydroperoxide (TBH), mutant ataxin-1-expressing cells have proved to be more prone to mitochondrial dysfunction than normal ataxin-1-expressing cells. These results suggest that polyQ-expanded ataxin-1-expressing cells increase the levels of ROS in HeLa cells (12).

Spinocerebellar Ataxia 3 (SCA3)/ Machado-Joseph Disease. Human SK-N-SH neuroblastoma cells stably transfected with full-length mutant Machado-Joseph disease (MJD) with 78 CAG repeats have been established to analyze the role of mutant ataxin-3 and mimic an early disease stage, as less than 1% of the mutant cells contain nuclear aggregates under basal conditions. To test the hypothesis that oxidative stress might contribute to the progression of the disease, TBH has been used to assess the oxidative tolerance of cells. It has been noticed that SK-N-SH-MJD78 cells, stably expressing expanded ataxin-3, are more susceptible to low concentrations of TBH (1 and 3 μM) up to 24h treatment than the parental SK-N-SH cells. Additionally, Western blot analysis has indicated that the protein expression of HSP27 has dramatically decreased in both neuronal and non-neuronal cells with expanded ataxin-3, which is possible to result in an increase of ROS in the cellular model. The same significant reduction of HSP27 has been further confirmed in the lymphoblastoid cell lines from two MJD patients, compared with that from a normal individual. Semiquantitative reverse transcription-polymerase chain reaction and microarray analysis have ruled out the possibility that the reduced HSP27 expression could be due to transcriptional repression of HSP27 gene, further supporting the evidence that expanded ataxin-3 increases the vulnerability to oxidative stress (13).

PRION DISEASES

According to "prion hypothesis" formulated by Prusiner in 1982, transmissible spongiform encephalopathies are caused by "novel proteinaceous infectious particles" corresponding to the scrapie isoform (PrPsc) of the normal host prion protein (14).

It has been suggested that the conformational conversion of normal, protease-sensitive, primarily α-helical form of prion protein (the cellular isoform, PrPc) into a pathogenic, protease-resistant, β-sheet-rich form of the protein (PrPsc) may be the result of imbalances in the level of copper. The changes in copper concentration have

altered prion protein (PrP) ability to act as an antioxidant by modifying its conformation. Truncated PrP could be a result of self-proteolysis by PrP when Cu^{2+} physiological concentration is too high (15). Moreover, it has been reported that PrPc undergoes a site-specific cleavage, both Cu^{2+}- and ph-dependent, of the octapeptide-repeat region on exposure to ROS such as H_2O_2 and superoxide ions (O_2^-). Such ROS cleavage might be involved in the formation of the scrapie isoform, as abnormal cleavage of PrPsc occurs into the octarepeat region (16).

The flexible amino-terminus of PrPc contains the octapeptide PHGGGWGQ, which is repeated four times and is among the best-preserved regions of mammalian PrPc. Proton nuclear magnetic resonance (NMR) spectroscopy has indicated that the histidine residues in each octarepeat are coordinated to the copper ion. It has been concluded that host PrPc gains a Cu,Zn-SOD-like antioxidant activity, dependent on copper incorporation (17). Immunoprecipitated PrPc from WT mouse brain has also mimicked SOD1 activity, which confirms that native PrP behaves as an antioxidant. Additionally, PrPc dependent SOD1 activity has been abolished by the precise deletion of the octapeptide-repeat region (18). Moreover, native PrPc, affinity-purified from mouse brain, has exhibited the same SOD1-like antioxidant activity, as determined by spectrophotometric assay. In conjunction, incubation of purified PrPc with PrP106-126, the neurotoxic peptide based on the sequence of PrPsc, has significantly inactivated the SOD1-like activity (19).

It has also been demonstrated that SOD1 activity varies with the level of PrPc expression. Thus, prion protein-deficient cells proved to be more sensitive to oxidative stress due to reduced SOD1 activity (20). In addition, SOD1 activity has proved to be significantly higher in cerebellar cells overexpressing PrP than for WT extracts. Moreover, the expression of PrPc may regulate Cu, Zn-SOD activity by influencing copper incorporation into the SOD1 molecule (21).

Furthermore, a study on 8 week-old prion protein knock-out mice (Prnp-/-) has emphasized a role for PrP in modulating oxidative homeostasis in vivo. In this regard, higher levels of oxidative damage to proteins and lipids have been found in the brain lysates of Prnp-/- as compared to WT mice of the same genetic background (22). PrP-/- neurons also proved to be significantly more susceptible to H_2O_2 toxicity than WT neurons after a 6 and 24 hour exposure. This result might be related to the significant decrease in glutathione reductase (GR), but not glutathione peroxidase (GPx), activity detected in PrP-/- neurons both in vitro and in vivo. These findings have been supported by PrP106-126 that has significantly inhibited GR activity and increased H_2O_2 toxicity in neuronal cultures (23).

ALZHEIMER'S DISEASE & PICK'S DISEASE

The presence of intracellular neurofibrillary tangles, containing hyperphosphorylated tau protein and apolipoprotein E, and of extracellular senile (neuritic) plaques, including non-soluble β-amyloid, ubiquitin, apoE, presenilins and alpha-antichymotrypsin, are considered hallmarks of Alzheimer's disease (AD) (24). AD is associated with an increased cerebral accumulation of amyloid beta-protein (Aβ), a 39-42 amino acid peptide. Soluble Aβ monomers aggregate to form antiparallel β-

pleated sheets as proved by circular dichroism studies (25).

As Aβ is considered to have a causal role in AD, the effect of oxidative stress on its metabolism within the cell has been studied. It has been reported that oxidative stress induced by H_2O_2 promotes intracellular accumulation of Aβ in human neuroblastoma cells through enhancing the amyloidogenic pathway (26). A possible role for LP in the pathogenesis of AD has also been suggested. It has thus been determined that membranes containing oxidatively damaged phospholipids promote beta-sheet formation in a 42-residue Aβ and accumulate Aβ significantly faster than membranes containing normal saturated phospholipids (27).

It has also been shown that H_2O_2 mediates Aβ-induced neurotoxicity, which explains why catalase, that degrades H_2O_2, protects the cells from β-amyloid toxicity. In addition, Aβ has induced the activity of nuclear factor kappa-light-chain-enhancer of activated B cells (NF-kappa B), a transcription factor thought to be regulated by oxidative stress (28). It has been suggested that amyloid peptides including Aβ may be toxic via a common oxidative mechanism and that their amphiphilic form, rather than the structure in β layers, may be the cause (29, 30).

Moreover, it has been emphasized that, under some conditions, toxic Abeta peptides Aβ1-40 and Aβ25-35 enhance transition metal-catalyzed oxidation of hydroxylamine derivatives (31). Several studies have also concluded that cortical or hippocampal synaptosomes isolated from AD brain or from rodent brain or rodent cultured hippocampal neurons incubated with Aβ1-42, Aβ1-40 or Aβ25-35 have increased protein oxidation; non-toxic reverse peptides have not caused protein oxidation (32).

It can thus be proposed the amyloid β-peptide-associated free radical oxidative stress model for neurotoxicity in AD: Aβ-initiated ROS react rapidly with several moieties in the plasma membrane and cause protein oxidation and LP; toxic products of LP, such as 4-hydroxy-2-nonenal and acrolein (2-propenal), having longer half-lives than free radicals, migrate to different parts of the neurons causing multiple alterations of cellular function such as sharp increases in intracellular Ca^{2+} and ultimately leading to neuronal death. Moreover, it has been suggested that methionine-35 (Met-35) is a key amino acid involved in Aβ radicalization, aggregation and neurotoxicity, since it is the most susceptible Aβ residue to oxidation in vivo, especially under oxidative stress conditions. Methionine oxidation to the sulfoxide leads to predominantly β-sheet conformation adopted by toxic Aβ. Examination of senile plaque-resident Aβ1-40 has detected a high proportion of methionine sulfoxide (33, 34).

However, it has been indicated that, rather than being a source of ROS, β-amyloid may be a modulator of ROS production (35).

Furthermore, the hyperphosphorylation of the microtubule-associated protein tau (τ) is considered a hallmark of tauopathies such as AD and Pick's disease. It has been hypothesized that oxidative stressors play a critical role in neurofibrillary pathology by activating stress-activated protein kinases such as p38 pathway that leads to τ phosphorylation in vitro and co-localizes with phosphorylated τ in vivo (36). It has been found that acrolein, a LP product from arachidonic acid, increases τ phosphorylation due to p38 stress-activated kinase (37).

PARKINSON'S DISEASE & DEMENTIA WITH LEWY BODIES

The synucleins (α, β and γ-synuclein) are a small family of proteins highly expressed in nervous tissue. An obvious link with Parkinson's disease (PD) has been established by showing that two missense mutations in the α-synuclein gene (A53T and A30P) are responsible for rare familial forms of the disease (38). In both PD and dementia with Lewy bodies α-synuclein accumulates in the form of fibrillar aggregates inside the Lewy bodies, cytoplasmic inclusions deposited within dopaminergic neurons.

Alpha-synuclein appears to increase ROS levels in dopaminergic neurons via more than one process. First, α-synuclein interacts with the dopamine (DA) transporter and facilitates its clustering at the plasma membrane. Consequently, DA uptake is accelerated leading to increased susceptibility to DA-induced apoptosis. Therefore, the re-uptake of more DA intracellularly can be a source of increased ROS due to DA metabolism (39). It has been indicated that over-expression of α-synuclein and especially its mutant forms exaggerates the vulnerability of neurons to DA-induced cell death through excess intracellular ROS generation (40). Additionally, transfection of cell lines with mutant forms of α-synuclein have increased the baseline levels of oxidative damage, reflected by decreased levels of GSH and enhanced levels of 8-hydroxyguanosine (8-OHG), protein carbonyls and LP (41).

It has also been shown that both full-length α-synuclein and its synthetic peptide fragment, when incubated in solution, have the ability to generate hydroxyl radicals upon the addition of ferrous ion (42). In conjunction, it has been revealed that oxidative stress can induce the aggregation of human α-synuclein (43). This bi-directional molecular pathway could create a vicious cycle of α-synuclein changes and excessive oxidative stress.

Moreover, it has been shown that parkin, an ubiquitin-protein ligase, interacts with α-synuclein; double staining of PD brains has illustrated that parkin and α-synuclein co-localize to the same pathological structures (both Lewy bodies and axonal spheroids) (44). In at least one patient, mutations in parkin have led to Lewy body formation as seen in sporadic PD. It has been investigated how overexpression of WT and mutant parkin proteins modulates proteasomal activity, ubiquitinated proteins accumulation, oxidative stress indices or antioxidant defenses. Increasing expression of WT parkin by gene transfection in two cell lines has led to increased proteasomal activity, decreased levels of protein carbonyls and a trend to a reduction in ubiquitinated protein levels. Transfection of the two cell lines with DNA encoding three mutant parkins associated with autosomal recessive juvenile parkinsonism have not altered antioxidant enzyme activities, namely SOD1, SOD2, catalase, GPx and GR, but have increased oxidative stress, as indicated by decreased levels of GSH, smaller increases in proteasomal activity and elevated levels of protein carbonyls and LP (45). Impairment of proteasomal function leads to free radical generation and oxidative stress (46). Therefore, altered activity of the ubiquitin-proteasome system, which degrades oxidatively damaged proteins, may play a key role in PD pathogenesis.

CONCLUSIONS

The present review provides strong evidence for a cause-effect relationship be-

tween oxidative stress and toxic proteins in the pathogenesis of neurodegenerative diseases.

In this regard, it has been suggested that a toxic gain of function of mutant htt arising from altered interactions with other proteins may lead to oxidative damage. In addition, transgenic mice over-expressing the mutated amino terminus of human htt have been shown to suffer the effects of increased oxidative damage. Moreover, studies have indicated that both polyglutamine-expanded ataxin-1 and ataxin-3 increase the vulnerability to oxidative stress.

It has also been emphasized that the loss of resistance to oxidative stress due to inactivation of the function of the normal form of prion protein, either due to conversion or through interaction with the pathogenic form of the protein (the scrapie isoform), may be important to the pathogenesis of prion diseases.

Furthermore, several studies have demonstrated not only that the oxidative processes can contribute to the aggregation of β-amyloid, but that β-amyloid itself can be considered a source of free radicals, thus supporting amyloid β-peptide-associated free radical oxidative stress model for neurotoxicity in AD.

Finally, this review points out that α-synuclein increases ROS levels in dopaminergic neurons and oxidative stress can induce the aggregation of α-synuclein.

THE INFLUENCE OF BAROREFLEX ACTIVATION THERAPY ON RENAL RESPONSES IN PATIENT WITH RESISTANT HYPERTENSION

It is widely accepted that renal system play an essential role in terms of long-term blood pressure regulation. Recently, a non-pharmacological theraphy represented by baroreflex activation has provided to be a promising alternative in order to reduce arterial pressure, particularly in patient with drug-resistant hypertension. A multicentre, double blind Rheos Pivotal Trial was designed to investigate the renal response and efficiency to prolonged baroreflex activation theraphy in patient with drug resistant hypertension. 322 patients aged 21 to 80 years, who had blood pressure ≥ 160/80 mmHg despite maximal tolerated therapy with ≥ 3 antihypertensive medication including a diuretic, were divided in two groups. Group 1 consisted of 236 patients who started baroreflex activation therapy 1 month after device implantation, whereas in the 86 patients from group 2 the device was activated 6 months later (deferred baroreflex activation theraphy). Serum creatinine, urine albumin/ creatinine ratio and estimated glomerular filtration rate were determined to asses renal function. The **results** showed that in group 1, serum creatinine increased from 78 to 84 μmol/L, and glomerular filtration rate decreased from 92 to 87 mL/min per 1.73m^2 at month 6, whereas albumin/ creatinine ratio did not change. Group 2 demonstrated similar renal responses at month 6 and month 12 as group 1. In **conclusion,** chronic baroreflex activation does not result in further decrease in renal function, suggesting that this non-pharmacological approach is safe, effective and promising. CORRELATIONS BETWEEN THE PRESENCE OF SIGMOID INTERVENTRICULAR SEPTUM AND INCREASED RELAPSE RISK OF STROKE IN HYPERTENSIVE PATIENTS (Abstract) **Objectives:** Comparison between cerebrovascular accident (CVA) relapse in hypertensive patients with sigmoid interventricular septum (SIS) and CVA relapse in hypertensive patients without SIS. **Materials and methods**: We selected 36 hypertensive patients, all of them complicated with previous CVA; 18 patients had SIS (Group A) and 18 patients didn't have SIS (Group B). The utilized methods were the following: clinical examination, electrocardiogram, transthoracic echocardiogram, biochemical findings and complete blood count, performed every 3 months, during 2 years of observation. Another method, addressed for CVA relapse patients, were cerebral computed tomography or magnetic resonance imaging .The recommended treatment was administered according to the European therapeutic guidelines. **Results**: 6 (out of 18) patients with SIS presented a CVA relapse and only 1 (out of 18) patient without SIS revealed a CVA relapse**. Conclusions**: Our results support recent conclusions from another publications: patients with SIS (an apparently benign condition, which is a part of the cardiac modifications usually discovered in elderly people) have a higher cardiovascular risk for acute events, than the patients without SIS.
Keywords: SEPTUM, HYPERTENSIVE, CEREBROVASCULAR

The physiological aging of the heart can reveal different aspects: myocardium atrophy, isolated amiloid deposits, mitral annulus calcification or the angulations of the interventricular septum to the ascending aorta (1). This last mentioned modification is known (in echocardiography) as sigmoid interventricular septum (SIS) and has been described in the medical literature since 1969 (2). Initially, SIS has been just a physiological variant of the heart aging. Afterwards, its occurrence has been explained as due to the ascending aorta dilation (in elderly people) and to the tilting of the aorta towards the interventricular septum. The basal portion of the interventricular septum is bulging into the left ventricular outflow tract (LVOT) and is becoming sigmoid-shaped, without significant clinical consequences (3). The same authors, Chan and Veinot, suggested the fact that the benign aspect of the SIS could have

hemodynamic consequences (the obstruction of LVOT) if the patient had left ventricular hypertrophy associated to SIS. A physiopathology impact could occur in some cases of heart aging. Several Japanese authors mentioned the age-related morphological changes of the inter-ventricular septum; a part of them had proven the fact that the thickening of basal portion of the interventricular septum was more significant in hypertensive patients than in normotensives, during follow-up spanning 10 years (4); other authors (5) remarked the basal portion of the interventricular septum hypertrophy (age-related) even in normotensives and no hypertrophy of the mid-ventricular portion. All these studies allowed a better understanding of the so-called "sigmoid interventricular septum" modification. A new concept about SIS developed during the last 10 years: a part of these patients could have dynamic obstruction into the left ventricular outflow tract, followed by hemodynamic consequences: a decreased coronary and/or cerebral perfusion pressure and an increased telediastolic left ventricular pressure. The clinical consequences generated by these hemodynamic changes consisted of: angina pectoris, lipothymia / syncope and dyspneea on effort. The treatment of the patients with SIS and dynamic obstruction in LVOT, using a medication which decreased the pressure gradient, became absolutely required. Clinical studies have proven the beneficial effect (decrease of the gradient and improvement of the symptoms) of the association between negative inotropic agents: betablockers and cibenzoline (6, 7) or betablockers and dysopiramide (8).

MATERIAL AND METHODS

The study included 36 patients (men: 60%; women 40%), aged between 65-79 years.

The inclusion criteria were: arterial hypertension (with an evolution of at least 10 years); ischemic stroke (past medical history); adherence to medical recommendations.

The exclusion criteria were: smoking or alcohol intake, at the beginning of the study; diabetes mellitus; association of severe medical diseases (neoplasia, severe heart/ renal/ respiratory/ liver failure).

The patients were monitored through the following methods (every 3 months, during 2 years): clinical examination, biochemical findings (serum creatinine, transaminases, glycemia, and lipid profile), complete blood count, electrocardiogram, transthoracic echocardiogram (we used a Fukuda Denshi UF-850 XTD echograph machine).Cerebral computed tomography or magnetic resonance imaging were performed only for the CVA relapse patients. We had 2 groups of patients, after echocardiography: group A- 18 patients with SIS and group B-18 patients. We selected (through echocardiography) these 18 patients with SIS, CVA and arterial hypertension, from 107 patients with arterial hypertension and previous CVA.

Clinical examination revealed the following: 1. angina pectoris (4 classes' classification, according to the Cardiology Canadian Society); 2.dyspneea (4 classes classification, according to the New York Heart Association); 3.vertigo; 4.sensibility and/ or motility disorders (confirmed by neurological examination); 5.blood pressure values (clinostatic and orthostatic positions). The CVA relapse has been clinically suspected; neurological consultation and cerebral computed tomography/magnetic resonance imaging were required for CVA confirmation.

Medical treatment (for group A,with

SIS) consisted of betablockers (Metoprolol succinate 50-200 mg/day), antiplatelet agents (Clopidogrel 75 mg/day), statins (Atorvastatin 40-80 mg/day or Rosuvastatin 20-40 mg/day), diuretic „thiazide-like": Indapamide 0.625-1.5mg/day, single or associated (with angiotensin converting enzyme inhibitors), into a fixed combination- Perindopril / Indapamide 2.5/ 0.625 mg or 5/1.5 mg, daily. Those patients with SIS and obstruction in LVOT received smaller doses of diuretics or fixed combination (for blood pressure control); this caution was necessary for the prevention of gradient increasing in LVOT, followed by redoubtable clinical consequences. We selected calcium channel blockers (Amlodipine 2.5-10 mg) and diuretics (Indapamide 0.625-1.5 mg/day) for group B- the hypertensive patients without SIS, according to European therapeutic guidelines in elderly hypertensive with CVA. We preferred beta blockers (Nebivolol 2.5-10 mg/day or Carvedilol 6.25-12.5 mg, twice daily) instead of calcium channel blockers, for those hypertensive with associated ischemic heart disease.

The patients without SIS and elevated blood pressure values, despite treatment with calcium channel blockers and diuretics, also received angiotensin converting enzyme inhibitors (Perindopril 2.5-10 mg/day) or sartans (Telmisartan 20-80 mg/day). All the patients without SIS (group B) received Clopidogrel 75 mg/day and statins (Atorvastatin 40-80 mg/day or Rosuvastatin 20-40 mg/day), considering previous CVA.

RESULTS

I. Group A. This group was formed by the following: group A_1 -7(out of 18) patients with SIS, LVOT obstruction and cardiovascular symptoms; group A_2- 4(out of 18) patients with SIS, symptoms and without LVOT obstruction; group A_3 - 7 (out of 18) patients with SIS and without symptoms or LVOT obstruction. All those 7 patients of group A_1 had cardiovascular symptoms: IIIrd class angina pectoris (angina on minor efforts) and IIIrd class dyspneea (dyspneea on minor efforts). Group A_2 had the following symptoms (fig.1): IIIrd class angina pectoris-2 patients; IInd classdyspneea-1 patient and IIIrd class angina pectoris plus dyspneea-1 patient. The patients of group A_3 had no cardiovascular symptoms, but they have SIS. All the 7 patients of group A_1 improved after 3 months treatment their effort tolerance (IInd class instead of IIIrd class). The patients of groups $A_2$and A_3 remained in the same situation concerning effort capacity.

II. Group B. This group was formed by the following: group B_1 (fig.2) -10 (out of 18) patients without SIS, had the following symptoms: IIIrd class angina pectoris-4 patients; IInd class angina pectoris - 2 patients; IIIrd class dyspneea-1 patient; IIIrd class dyspneea plus angina pectoris- 3 patients; group B_2-8(out of 18)patients without SIS and without cardiovascular symptoms. Five (out of 7) patients from group B_1 had a favorable evolution of cardiovascular symptoms (they passed from IIIrd class to IInd class). Concerning the 8(out of 18) patients of group B_2 we noticed the same clinical condition throughout the 2 years study.

About CVA relapse, we revealed the fact that 6 out of 18 patients (33%) with SIS (from group A) had a CVA relapse, during 2 years study. All these 6 patients had LVOT obstruction, suggesting a strong correlation between the presence of hemodynamic significant gradient and CVA

relapse risk. The CVA relapse rate was significantly reduced - 5% - (1 out of 18 patients) among the patients without SIS (group B).

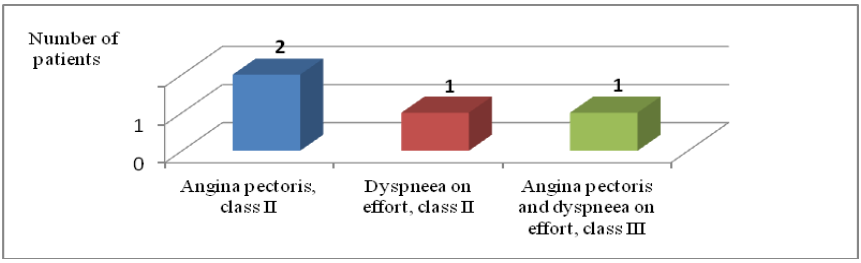

Fig.1. The symptoms of the patients with SIS and without obstruction in LVOT

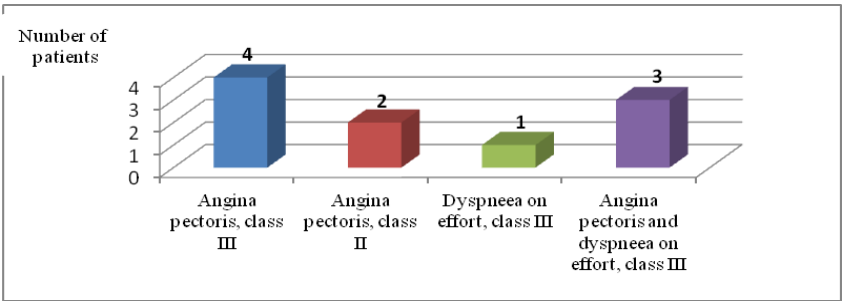

Fig. 2. The symptoms of the patients without SIS

Echocardiography revealed obstruction in LVOT (mild / moderate obstruction: LVOT gradient was between 25-52 mmHg), in all 7 patients of group A_1. All these 7 patients recorded a qualitative echocardiographic improvement after the treatment: the highest LVOT gradient was34 mmHg (after 3 months), comparing with the highest gradient-52 mmHg (at the beginning of the study).

The biochemical findings revealed the following aspects: 1) 2 patients from the group A with SIS maintained (at 3 months revaluation) a lipid profile associated with high cardiovascular risk (total cholesterol≥ 230 mg/dl). These 2 patients required the addition of Fenofibrate 160 mg to the previous statin and they had a favorable evolution of cholesterol values (at 6 months revaluation).

They were part of the 6 patients group with the relapse of the CVA; 2) at the 3 months revaluations of the serum creatinine, renal dysfunction has been precociously revealed in 3 (out of 18) patients from group B without SIS (treated with Perindopril 10 mg). We stopped Perindopril administration for these patients; replacing that medication with betablockers (the patients also continued the diuretics and calcium channel blockers).

We haven't discovered right or left renal artery stenosis at these patients (there was the possibility they had atherosclerotic stenosis of the small renal arteries, undetectable with echography).

Cerebral computed tomography and magnetic resonance imaging proved the CVA relapse in all 7 patients clinically suspected: 6 (out of 18)-33% from group A

and 1 (out of 18)-5% from group B.

DISCUSSION

The clinical studies have proven the fact that an apparent benign aspect of heart aging, like sigmoid interventricular septum, could precipitate severe obstruction in LVOT, under special circumstances. The hemodynamic worsening (vasoplegic syndrome determined significant gradient in LVOT) after lumbar anesthesia, in patients with SIS, was an example for this situation (9). Another clinical situation which could develop the aforementioned gradient was anemia associated with SIS; anemia could induce hyperkinesias (with powerful ventricular contractility) and could decrease blood flow volume, both of them leading to sudden increase of the LVOT gradient (10). Our study has related results with other publications (11, 12): an apparent physiological heart aging situation – SIS - could increase the risk for ischemic cardiovascular events (cerebral or myocardial) and medical intervention could decrease this risk.

CONCLUSIONS

Our study noticed that increasing LVOT gradient in SIS patients with LVOT obstruction lead to a higher relapse of CVA (33%- 6 from 18 patients) than in patients without SIS (5%-1 from 18 patients). Despite medical treatment which had benefices towards LVOT gradient, those 6 patients with LVOT obstruction unfortunately developed CVA relapse.

That means they had done some mistakes according life style and behavior: they had a sudden increasing in LVOT gradient, due to heavy efforts or psychological distress. Those patients who performed heavy efforts developed a sudden more powerful left ventricle contraction, so an increasing LVOT gradient and decreasing cerebral blood flow; therefore they made an ischemic CVA under these circumstances (medical treatment could not protect the patient because the effort was too strong).

Those patients who had a major psychological distress had a sudden cathecolamines releasing, which provoked a more powerful contraction of left ventricle, followed by the same consequences as aforementioned heavy efforts.

After a detailed anamnesis, we discovered one of this etiology at all our patients with CVA relapse. Future studies, including more patients, are necessary to complete these observations.

INTRAVASCULAR LARGE B-CELL LYMPHOMA

Intravascular lymphoma was first described in 1959 by Pfleger and Tappeiner in Germany. It was described as a neoplasm of the vascular endothelium, due to intravascular growth of malignant cells, hance the initial name of the disease as "angioendotheliomatosis proliferans systemisata". In 1986 Sheibani et al proved, via immunohistochemical investigation, that the cells of intravascular lymphoma were of lymphoid origin and described the disease as angiotropic (intravascular) large-cell lymphoma. In 2008, the World Health Organization defined intravascular large B-cell lymphoma (IVLBCL) as a type of extranodal large B-cell lymphoma where growth is restricted to the lumina of vessels, particularly capillaries. Intravascular large B-cell lymphoma is rare, occurring at an estimated frequency of less than 1 person per million. Two forms have been described: classical, also known as Western form, with a cutaneous variant; and an Asian form occurring more frequently in the Far East. Intravascular lymphoma is most frequently a disease of B lymphocytes, although rare cases of thymus-cell (T-cell) and natural killer–cell disease have been reported; the World Health Organization considers these cases to be a separate entity. Intravascular large B-cell lymphoma is aggressive, and has historically been a rapidly fatal malignancy when diagnosis and treatment is delayed. Intravascular large B-cell lymphoma is a rare type of extranodal large B-cell lymphoma. It tends to occur in elderly patients, occurs with only slight predilection for male sex, and is without known risk factors. Accurate diagnosis is elusive, requires strong clinical suspicion, and tissue sampling and microscopy of at least 1 of what is typically several disseminated lesions. Microscopy will demonstrate large B cells sequestered within the intravascular spaces; these cells inconsistently express several of the typical B-cell antigens, with CD79a, CD20, MUM1/IRF4, and CD19 being the most commonly expressed. With the exception of a cutaneous variant, IVLBCL is aggressive and carries a grim prognosis, although the prognosis has improved with recent introduction of rituximab to combination chemotherapy regimens. These anthracycline-based or CHOP-like regimens plus rituximab have resulted in improvement of clinical course, and prolonged remission and survival (Dennis E. Orwat,; Nicholas I. Batalis, Intravascular Large B-Cell Lymphoma, *Arch Pathol Lab Med*. 2012;136:333–338).

GASTROESOPHAGEAL REFLUX AND METABOLIC SYNDROME *(*Abstract) The **aim** of our study was to evaluate gastric, duodenal and gallbladder motility disorders in patients with gastroesophageal reflux disease (GERD) and metabolic syndrome. **Material and methods**: We studied 128 patients with GERD divided into two groups: first group with metabolic syndrome and the second without metabolic syndrome. By abdominal ultrasound we monitored our patients for the gastric emptying rate, the duodenal motility and the nonlithiasic pathology of gallbladder (cholesterolosis). **Results**: We found that patients with metabolic syndrome had three kind of abnormal motility disorders including stomach, duodenum, and gallbladder. The patients without metabolic syndrome we found only two abnormal motility disorders: of the duodenum and gallbladder. Hyperglycemia and high serum cholesterol level in the first group were correlated with stomach, duodenum and gallbladder abnormal motilities. In our opinion metabolic syndrome can aggravate gastroesophageal reflux disease due to these metabolic abnormalities. **Conclusions**: We consider that treatment of reflux disease in these particular cases must also involve measures to correct metabolic disorders. **Keywords**: METABOLIC SYNDROME; CHOLESTEROLOSIS GALLBLADDER GASTROESOPHAGEAL REFLUX.

Metabolic syndrome is a cluster of metabolic disorders defined as the presence of an increased waist circumference and two of the following components: high blood pressure, hypertriglyceridemia, low levels of high density lipoprotein (HDL)-cholesterol, or diabetes mellitus (DM)/ hyperglycemia (1). This syndrome is associated with high risk for cardiovascular diseases and has become one of the major health problems worldwide (1).

Gastroesophageal reflux disease is characterized by the presence of esophageal mucosal injury or reflux symptoms caused by the abnormal reflux of gastric content into the esophagus (2).

Several studies have shown the relationship between obesity, erosive esophagites and GERD symptoms (3). Also other studies demonstrated that metabolic syndrome was associated with GERD (4) through the precise mechanisms have not been fully determined. However, literature on whether metabolic syndrome influences the gastric, duodenal and gallbladder motility in patients with GERD is scant.

The aim of this study was to determine whether metabolic syndrome influences the gastric, duodenal and gallbladder motility and aggravates the symptoms in patients with GERD.

MATERIAL AND METHODS

Patients

We conducted a prospective case-control study, on patients admitted in a tertiary hospital, from January 2010-December 2012, diagnosed with GERD.

We excluded patients with prior gastric surgery, gastric cancer and peptic ulcer.

After a medical history was taken, all patients had physical examination, hematological and biochemical blood tests, an abdominal ultrasound and completed a questionnaire.

Patients were diagnosed with metabolic syndrome if they had an increased waist circumference and two of the following component: high blood pressure (≥130 mmHg systolic or ≥85 mmHg diastolic), hypertriglyceridemia (≥150 mg/dl), low levels of HDL-c (≤40 mg/dl in males or ≤50 mg/dl in females), or DM/hyperglycemia (1).

All participants completed a validated questionnaire that identified reflux symptoms, such as irritating heartburn and/or regurgitation experience during the preceding year (5). Values between 0-7 points were associated with less probable GERD, a score between 8-10 points revealed GERD with discomfort and unpleasant symptoms and a score of 11-18 points characterized GERD with discomfort and severe symptoms.

Measurements

The sonographic examination was performed using a Philips XD11XE ultrasound machine, using a C5-2 transducer.

The gastric motility was assessed by the method proposed by Dareiche and Osman (6). The method considers that gastric volume is directly proportional with antral area (Aa). Gastric emptying rate (GER) represents the percentage of Aa reduction measured 15 minutes and 90 minutes after a standard meal. Normal values for Aa are 489 mm^2 (377-745 mm^2) for 15 minutes and 166 mm^2 (124-279 mm^2) for 90 minutes. The average GER value is 63% (58-69%) (6).The longitudinal diameter (D1) and anteroposterior diameter (D2) of the antral section were obtained placing the traducer in a longitudinal position at the level of the abdominal aorta and the left hepatic lobe. The formula for Aa is: Aa= 3,14 x D1xD2/4 and it was applied for Aa measured at 15 minutes and at 90 minutes. GER =(Aa90'/Aa15'-1) x 100 (7). We used a standard meal which contained 50g carbohydrates, 15g proteins and 12g lipids.

The duodenal motility was assessed by sonographic observing of peristaltic and antiperistaltic waves. This type of movements could be observed during the physiological phase of duodenal digestion and if they are enhanced it could have pathological consequences.

Gallbladder colesterolosis was defined using ultrasound criteria described by Sporea (7).We calculated the gallbladder volume before and after Boyden meal and then we calculated the ejection ratio (ER) of gallbladder by the formula: E.R= V1-V2/V1x 100, where V1 is gallbladder volume before Boyden meal , V2 is gallbladder volume after Boyden meal. The formula for gallbladder volume is V=0,5x Lxl x g, L is the length of gallbladder, l is the width of gallbladder, g is the thickness of gallbladder wall. Normal values are 50-60%.

Statistical analysis

Statistical analysis was performed using the χ^2 test for comparison of discrete variables and the *t*-test for comparison of continuous variables. The continuous variables measured in this study were expressed as the mean±SD. Correlations were performed

using Spearman correlation test. Linear and logistic regression were used to calculate odds ratio (OR) and 95% confidence interval (CI). A two-tailed p value of<0.05 was considered statistically significant.

This study was carried out in accordance with the Declaration of Helsinki. Written informed consent was obtained from all patients.

RESULTS

In this study we included 128 patients diagnosed with GERD. Fifty-nine patients had metabolic syndrome and 69 patients represented the control group, without metabolic syndrome (tab. I).

TABLE I

Baseline characteristics of the study groups

	GERD with metabolic syndrome (n=59)	GERD without metabolic syndrome (n=69)	*p*
Age (years)	41±2.3	40±2.9	0.553
Sex (M/F)	35/24	40/29	0.486
BMI (kg/m^2)	34.77±5.2	29±4.4	0.036
Smoker (%)	58	55	0.125
Triglyceride (mg/dl)	255±45.2	159±32.9	<0.0001
LDL-col (mg/dl)	176±21.4	112±20.3	<0.0001
Cholesterol (mg/dl)	290±43.6	236±35.3	<0.0001
HTA(%)	78	51	<0.0001
DM (%)	39	16	<0.0001
Hiatal hernia (%)	75	68	0.058
Esofagitis (%)	24	19	0.244
GERDQ questionnaire (points)	14±2.4	9±1.2	<0.0001

Abbreviations: BMI: body mass index, LDL: low density lipoproteins, HTA: arterial hypertension, DM: diabetes mellitus, GERDQ: gastroesophageal reflux questionnaire.

The mean age was 40.5 years and 58.5% of the subjects were men.

We found a significant increased in the mean BMI, systolic blood pressure, glucose, cholesterol in patients with metabolic syndrome compared to the controls.

Patients with GERD and metabolic syndrome had a higher GERD questionnaire score than controls (p=0.033), corresponding with more severe reflux disease.

The presence of metabolic syndrome determined a high rate of cholesterolosis, an increased duodenal motility and ER of gallbladder, and decreased gastric emptying in cases than controls (tab. II). None of the controls had low values of GER.

In group with metabolic syndrome we found three kind of abnormal motility disorders: low GER values (100%); enhanced duodenal motility (40%) and high values of gallbladder ER (42%). In the control group we found only two kinds of motility disorders: enhanced duodenal motility 16% and high values of gallbladder ER. We diag-

nosed gallbladder cholesterolosis in cases 45% than controls in 10%.

TABEL II

Odds ratio for metabolic syndrome and GERD by multiple logistic regression

Metabolic syndrome and GERD		
	OR	CI 95%
Decreased GER	2.32	1.36-5.48
Increased duodenal motility	1.58	0.97-5.63
Colesterolosis	1.21	0.83-7.45
Gallbladder Er>50-60%	0.98	0.53-2.77

Abbreviations: GERD: gastroesophageal reflux disease, GER: gastric emptying rate, ER: emptying rate.

In patients with GERD and metabolic syndrome we found an inverse correlation between serum glucose and GER value, and a direct correlation between cholesterol values and duodenal motility.

DISCUSSION

GERD is caused by the abnormal reflux of gastric contents into the esophagus (4). Its occurrence is related to multiple factors, such as gastric acid secretion, hiatal hernia, lower esophageal sphincter (LES) function, esophageal motility, and esophageal perception (2). In addition, dietary habits, such as alcohol intake and eating foods with high components of fat or in large portions, may cause not only visceral fat accumulation, but also frequent gastroesophageal reflux due to a reduction in LES pressure and an increase in the number of transient LES relaxations (TLESR) (2).

In the present study we investigated the relation between metabolic syndrome and gastric, duodenal and gallbladder motility disorders, and our results clearly demonstrated that the presence of metabolic syndrome was associated with decreased gastric emptying, and increased duodenal motility. In addition, the presence of metabolic syndrome was suggested to worsen reflux symptoms (3) fact confirmed by our study.

All cases with cholesterolosis had high values of gallbladder ER and associated enhanced duodenal motility. This fact means that the bile which is rich in cholesterolosis reaches the duodenal lumen quickly and can induce the enhanced duodenal movements which sometimes opens the pylorus and allows the reflux of duodenal juice containing bile and pancreatic juice in the stomach. If the gastric motility is low (low GER values) the gastroesophageal reflux is getting worse.

In the first group patients with three motility disorders had high values of GERDQ (11-18 points) meaning that the reflux was severe. Controls, with only two abnormal motilities disorders, had lower values of GERDQ (8-10 points) which means that the gastroesophageal reflux was not severe as in the first group.

Previously, Chung et al. (8) demonstrated that the presence of metabolic syndrome and visceral obesity in a Korean population were significant risk factors for the occurrence of reflux esophagitis. The results of our study appear to fit well with those findings. An augmented effect of dyslipidemia on the prevalence of reflux esophagitis was also demonstrated in the study of Chung et al. (8), though the precise mechanism of the dyslipidemia-induced high prevalence of GERD and reflux esophagitis remains unclear. We demonstrated that high cholesterol levels imply high excretion into biliary tract followed by development of gallbladder cholesterolosis. The bile rich in cholesterol reaches the duodenum and induces enhanced

motility. Therefore, the intake of meals with a high level of fat might induce not only dyslipidemia, but might also lead to aggravate GERD symptoms.

In the present study, low values of GER were statistically related with high values of blood glucose. It is known that GERD prevalence in patients with DM, is higher in comparison with that in healthy individuals, and is reported to be caused by a decline in salivary secretion, delayed gastric emptying-induced increases in TLESR, and an increase in gastroesophageal reflux (3, 4). In our study, we observed that low values of GER in the first group were similar to those from diabetic patients (7) in which the vegetative vagal neuropathy induced delayed gastric emptying.

CONCLUSIONS

Our results indicate that metabolic syndrome enhanced GERD symptoms by gastroduodenal and gallbladders motility disorders. These results allow us to assert that in all cases with gastroesophageal reflux which associates metabolic syndrome the treatment must be addressed also to this complex entity.

EFFECTIVENESS OF THE IMMUNOCHEMICAL FECAL TEST (FIT) FOR DETECTION OF ADVANCED ADENOMAS IN COLORECTAL CARCINOMA SCREENING IN AN ASYMPTOMATIC POPULATION (Abstract): **Aim:** The aim of the study was to evaluate the benefit of the immunochemical fecal blood test (FIT) for detection of advanced adenomas. **Material and methods:** We have conducted a screening study on a average-risk cohort of subjects, aged 50 –74 years. We used a rapid quantitative FIT to perform the screening. Colonoscopy was recommended in all participants with positive FIT. We assessed the participation rate and analyzed advanced adenomas detected in the screening examinations. **Results:** Our study enrolled 1111 asymptomatic participants. Immunochemical test results were positive in 72 subjects (6.5%). Colonoscopy was performed by 50 /72 (69.4%) subjects. The detection rate for advanced adenomas was 2.2%. A total number of 28 advanced adenomas were detected in 24 subjects, meaning 1.2 advanced adenoma/subject. Analyzing the 3 characteristics of advanced adenomas, we observed in our study that 25/28 adenomas (89.3%) had sizes ≥ 10 mm, 11/28 adenomas (39.3%) were tubulovillous/villous and 19/28 adenomas (67.9%) had high dysplasia. The majority of advanced adenomas were found in the left colon as compared to the right colon: 71.4% vs. 28.6%, p=0.0008. **Conclusions:** In our study was obtained a 2.2% detection rate for advanced adenomas, most of them (71.4%) being located in the left colon. The dominant feature of advanced adenomas detected was the size ≥ 10 mm (89.3% of cases). **Keywords:** IMMUNOCHEMICAL FECAL TEST, ADENOMAS, COLORECTAL CARCINOMA, SCREENING.

Colorectal cancer (CCR) is a major cause of mortality in the developed countries, with a 6% risk to develop the disease during life, with an incidence of more than one million new cases per year and with a long term survival of 50% (1).

Detecting the early stages of CCR and adenomas in an apparently healthy population using the screening tests reduces incidence and mortality due to colorectal car-

cinoma. Noninvasive testing as fecal occult blood tests (FOBT) is now widely accepted as a screening tool for detecting CCR (2). At the beginning the guaiac fecal occult blood tests were used for screening but due to their low sensitivity and specificity (they are not specific for human hemoglobin and they need dietary restrictions) they are less used nowadays (3).

The fecal immunochemical test (FIT) is considered a superior screening test, because of its better reproducibility and acceptance. Detection rates for advanced adenomas and cancer are higher compared to guaiac fecal occult blood test (gFOBT) (4). Therefore the American Cancer Society has replaced the guaiac based test with immunochemical tests as a screening tool for CCR (5). A better sensitivity in detecting CCR in early phases when the disease is asymptomatic has been demonstrated by fecal immunochemical test than gFOBT (1). Data from Saito demonstrated a sensitivity of 67-89%% in detecting CCR using immunochemical test compared with 33-37% using Hemoccult. A reduction in CCR mortality with 60% was demonstrated with annual screening (6).

The aim of the study was to evaluate the benefit of the FIT for detection of advanced adenomas knowing their malignant potential.

MATERIAL AND METHODS

Our study included a cohort of average risk persons, meaning asymptomatic subjects aged between 50 and 74 years. To limit the percentage of FIT false positives results the following subjects were excluded subjects with adenoma or colonic carcinoma or with family history of adenoma or colonic carcinoma (first – degree relatives), subjects with inflammatory bowel diseases, people that took part in a screening program and performed one of the screening methods accepted by the international guidelines in the last years (2 years for FOBT, 5 years for virtual colonoscopy/barium enema/flexible sigmoidoscopy and 10 years for colonoscopy). Subjects with a short life expectancy (less than 10 years) were also excluded.

All subjects included in our study signed an informed consent; the study was approved by the local Ethics Committee and was in accordance with the Helsinki Declaration of 1975.

The stool sample was collected in a clean dry screw-top container according to the instructions that they have received. The stool sample was handed to the laboratory on the same day of the collection or within the first 24 hours. The test format of HEM CHECK-1 (VedaLab, France), used in our study, employs the standard antibody/antigen lines of capture, typically with a control line to interpret a positive and negative result. Test results were sent to the participant, physician and medical screening program coordinator.

Patients with positive FIT were sent to the Gastroenterology Department of Arad County Hospital to set an appointment for the colonoscopy. The Gastroenterologist explained to the subjects the benefits and the risks of performing a colonoscopy and if needed, a polypectomy. Preparation for colonoscopy was done with polyethylene glycol. All colonoscopies were performed under sedo-analgesia. Anesthesia, colonoscopy and polypectomy were performed only after obtaining the written consent from the patient. Administration of anticoagulant therapy, non-steroidal anti-inflammatory drugs or clopidogrel was stopped in the last 5-7 days prior to the

endoscopic procedure. The colonoscopy result includes the number of polyps, their size (≤ 5mm, from 5-9 mm, and ≥ 10 mm) and their location. The histopathology result of the biopsy mentions besides the size (≥ 10 mm), the tubulovillous or villous structure and the high grade mucosal dysplasia of the adenoma to confirm the diagnosis of advanced adenoma.

We used the term advanced adenomas for adenomas with at least one of these characteristics: size ≥ 10 mm and / or high-grade mucosal dysplasia and / or with a villous structure of ≥ 20% (tubulovillous, villous).

Statistical analysis was performed using the MedCalc Software, version 12.4.0 (MedCalc, Belgium). The distribution of the numerical variables was first tested by the Kolmogrov-Smirnov test. In case of numerical variables with normal distribution mean value and standard deviation were calculated, while in case of non-normal distribution median values and range interval were presented. Qualitative variables were presented as numbers and percentages. The Fisher's exact test was used for the comparison of two proportions expressed as a percentage. 95% confidence intervals were calculated for each predictive test. A *p*-value less than 0.05 were regarded as significant for each statistical test.

RESULTS

Our study enrolled 1111 asymptomatic participants with mean age 61.4 ± 12.8 years, 461 (41.5%) men and 650 (58.5 %) women. FIT results were positive in 72 (6.5%) persons with mean age 62.1±11.9 years, 34 (47.2%) men and 38 (52.8%) women. The mean age of women with positive FIT was similar with the mean age of men with positive FIT: 62.3±12.1 years vs. 61.9±12.1years, p=0.76.

Among the 72 participants with positive FIT, 50 (69.4.%) accepted to perform a colonoscopy. The others refused colonoscopy or delayed this investigation. Advanced adenomas were detected in 24 subjects (2.2%), 16/24 subjects (66.7%) were men and 8/24 subjects (33.3%) were women. The mean age of men with advanced adenomas was similar with that of women detected with advanced adenoma: 63.5±11.4 years vs. 62.6±12.1 years, p=0.85. A total of 28 advanced adenomas were detected in these subjects, meaning 1.2 advanced adenoma/ subject. Association of advanced adenomas with colorectal cancer was met in 5 patients (20.8%) (tab. I).

TABLE I

The distribution of advanced adenomas according to the age

Age group (years)	Total investigations		Advanced adenomas		Number of advanced adenomas	Number of advanced adenomas /subject
	number of subjects	%	number of subjects	%		
50-54	225	20.3	3	1.3	3	1
55-59	256	23.0	3	1.2	4	1,3
60-64	254	22.9	6	2.4	7	1.2
65-69	178	16	6	3.4	7	1.2
70-74	198	17.8	6	3.0	7	1.2
Total	1111	100	24	2.2	28	1.2

Analyzing the 3 characteristics of advanced adenomas, we observed that 25/28 adenomas (89.3%) had sizes ≥ 10 mm, 11/28 adenomas (39.3%) were tubulevillous/villous and 19/28 adenomas (67.9%) had high dysplasia.

In our study 7/28 (25%) advanced adenomas showed a single characteristic: 5 adenomas had size ≥ 10 mm , one adenoma had tubulovillous/villous structure and one adenoma was with high grade dysplasia. Two characteristics were found in 15/28 (53.6%) adenomas: 11 adenomas had size ≥ 10 mm and high grade dysplasia, 3 adenomas had size ≥ 10 mm and had tubulovillous/villous structure and one adenoma had tubulovillous/villous structure and high grade dysplasia. All 3 characteristics were found in 6/28 (21.4%) adenomas.

Analyzing advanced adenomas by its location we observed that most of them were found in the left colon as compared to the right colon: 71.4% vs. 28.6%, p=0.0008 (tab. II).

TABLE II

Distribution of advanced adenomas at colonoscopy

Location	Adenomas	
	Number	%
Rectum	6	21.4
Sigmoid colon	12	42.9
Descending colon	2	7.1
Transvers colon	5	17.9
Ascending colon	3	10.7

DISCUSSION

The purpose of screening for CCR is to reduce the morbidity and mortality because the prolonged evolution of the adenoma to carcinoma (10-15 years) is well known (7). Colonoscopy is the first choice screening option recommended by the international guidelines because of its high sensitivity/specificity and therapeutic utility for advanced adenomas, but it is costly and it requires specialized personnel and corroborated with the risks that are involved (like perforation) (8) make this method a difficult one to be implemented in a national screening program in our country.

The aim of the present paper was to evaluate the effectiveness of FIT in detecting advanced adenomas as the removal of these lesions could be considered a warrant of invasive cancer prevention. We chose the FIT because among the other non invasive test, such as the guaiac based fecal test, it proved better sensitivity, specificity and a higher compliance (9). We studied an average-risk population cohort, aged 50-74 years, using a rapid qualitative FIT, Hem Check 1, produced in France by VedaLab.

In our study the detection rate of advanced adenomas was 2.2%, similar values being obtained in other studies (9,11) and remained considerably higher compared to the guaiac-based fecal test detection rate (10,11).

In this study we detected 28 advanced adenomas. Dominant characteristics of advanced adenomas were size ≥ 10 mm (89.3%) and high-grade dysplasia (67.9%). 39.3% of advanced adenomas contained tubulovillous/villous. Large size, high-grade dysplasia and villous pattern are pathological characteristics that are known to increase the probability of malignant

transformation (12). It is known that polyp's ≥ 10 mm have a 1% malignancy rate per year and they turn into cancer in 24% of cases. Adenomas less than 10 mm may develop invasive cancer in less than 5 years extremely rare (13). Some studies (14, 15) proved that greater size of the adenomas determined higher rate for detection of advanced adenomas or cancer in follow–up colonoscopies and a villous pattern of more than 20% is not a constant risk factor for detecting advanced adenoma during follow –up colonoscopy (1). We obtained similar values compared to the data published by Yang et al evaluating the effectiveness of the FIT in a 5919 cohort study in 2011 when they analyzed the characteristics of the advanced adenomas (16).

Our data analysis supports the hypothesis that FIT is more efficient for detecting left-sided advanced adenomas than right-sided advanced adenomas The location of advanced adenomas in our study was mainly in the left colon 71.4% vs 28.6% the right colon ($p<0.0008$). The differences in detecting advanced adenomas in left and right colon are similar to the findings reported by Morikawa et al (2005) regarding immunochemical FOBT (17) and is also supported by other studies, one of them conducted by Haug et al. in 2011 using FIT (18), and another one reporting a test performance of a guaiac-based FOBT (19). Most studies proved a better efficiency in detecting left sided lesions (rectum, sigmoid, descending colon, splin flexure) than in the right colon (transverse, ascending colon,caecum) probably because of the stool consistency and because the blood is more homogeneous distributed in the right sided colon and is more superficial in the left colon (18).

Authors of the "European guidelines for quality assurance in colorectal cancer screening and diagnosis guidelines" (1) gathered information from several studies stating that older age comes with increased risk of detecting advanced adenomas (15,20). Our study cohort showed a greater rate of advanced adenoma in the group age ≥ 60 years old, but should be specified that a relatively small number of FIT positive subjects were included in each group. Although the majority of the studies (1) analyzing the detection rate of advanced adenomas in older age showed the same conclusions, advanced age is not an indication for more intense surveillance because of the slow progression of advanced adenomas to cancer (1). In our study we detected a greater number of advanced adenomas in men; similar values were obtained in some studies (15) but not in all (20).

CONCLUSIONS

In this study we obtained a 2.2% detection rate for advanced adenomas, most of them (71.4%) being located in the left colon. The dominant feature of advanced adenomas detected was the size ≥ 10 mm (89.3% of cases). Knowing that, positive FOBT and, more useful – FIT combined with cut – off hemoglobin levels, are recommended as methods which are correlated with colonic diseases – especially polyps and cancer.

CLINICAL, BIOLOGICAL AND EPIDEMIOLOGICAL ASPECTS OF INFLAMMATORY BOWEL DISEASES IN NORTH-EAST ROMANIA (Abstract): **Aim:** Inflammatory bowel diseases (IBD) are chronic conditions of unknown etiology with increasing incidence in South-East Europe. The epidemiological characteristics, clinical, biological and endoscopic profiles are very different worldwide, with little data existing from Moldova region. This study aims to characterize IBD in North-East Romania from the mentioned points of view. **Material and methods:** All patients with Crohn's disease or ulcerative colitis (UC) admitted to a tertiary hospital during a three year interval were retrospectively analyzed in terms of epidemiological characteristics. All IBD patients hospitalized during 2010 were complexly analyzed by noting the type and form of disease, the biological picture, the clinical and endoscopic scores. **Results:** UC represents 77% of all cases (one of the highest values of the recent studies). Age at onset is higher in the studied region, with the average over 40 years. In UC the forms of severity and extension are uniformly distributed, but in Crohn's disease there is a predominance of colonic forms and the number of complicated cases is high - over 50%. The parameters with the best correlation with endoscopic scores were the clinical Mayo score for UC, serum C-reactive protein and fibrinogen. **Conclusions:** There is a definite predominance of UC in North-East Romania, but Crohn's disease tends to present an increased number of complications. The age of onset of the two diseases is high. There is a good correlation between the clinical and biological scores with endoscopic activity, but without this assessment inflammation may be underestimated. Systematic exploration of the small bowel may increase detection of ileal manifestations. **Keywords:** INFLAMMATORY BOWEL DISEASES, ULCERATIVE COLITIS, CROHN'S DISEASE, EPIDEMIOLOGY, MONTREAL CLASIFICATION.

Inflammatory bowel diseases (IBD) are chronic conditions of uncertain cause comprised of two distinct entities- ulcerative colitis (UC) and Crohn's disease (CD). If UC only affects the colon and rectum by continuous inflammation limited to the mucosa, CD may involve any segment of the digestive tract (most commonly the ileum and the colon), inflammation being discontinuous and extended in depth (1). With an incidence of tens to hundreds per 10^5 people and a prevalence of a few hun-

dreds, IBD represent an important cause of morbidity and impaired quality of life especially in young and middle-aged patients, by the chronic relapsing nature and lack of curative treatment (2). There is important variation worldwide in the incidence, prevalence, clinical and evolving features according to geographic region, ethnicity and race (3). It is estimated that the incidence in South-Eastern Europe is slightly increasing, especially for CD, compared to Northern and Western Europe, where it is stabilized (4,5).

The few published studies for Romania have shown a lower incidence compared to the neighboring regions, a higher mean age and the prevalence of mild to moderate forms of disease. However, the data are slightly contradictory and there are methodological difficulties (6, 7).

This study aims to evaluate from epidemiological, clinical, biological and endoscopic perspective all cases of inflammatory bowel disease submitted to a tertiary medical center within three years.

MATERIAL AND METHODS

This study represents a retrospective analysis of all cases diagnosed with inflammatory bowel disease hospitalized in the Center of Gastroenterology and Hepatology from the "St. Spiridon" University Hospital between 1st January 2008 and 31st December 2010. Epidemiological data as disease type, number of cases, age and gender of patients were recorded. Cases classified as indeterminate colitis were interpreted as UC or CD considering the dominant clinical, endoscopic and histological characteristics. A sample composed of all patients hospitalized during the year 2010 was complexly analyzed by studying data recorded in the medical observation documents and analyzing the colonoscopy registers and video recordings, noting the following parameters: type of disease and its duration, main symptoms, personal and family history (including possible extra-intestinal manifestations), classical inflammation tests values (ESR, fibrinogen, C-reactive protein - CRP), the extent and severity of UC and Crohn's disease location and behavior according to the Montreal criteria (8).We also calculated the Mayo Clinical score (for UC) (9) and Harvey-Bradshaw index (for Crohn's disease) (10) and endoscopic Mayo score and respectively simple endoscopic score for Crohn's disease (SES-CD) (11). Finally we assessed the degree of correlation of endoscopic scores with clinical scores and biological parameters of inflammation. Data analysis was made using *Microsoft Excel* and *Minitab* software.

RESULTS

The total number of patients (excluding multiple hospitalizations within one year) and the proportion of the two types of disease are illustrated below (fig. 1).

There is a clear predominance of UC, this represents 77% of all cases. Most affected age groups were 25-35 and 35-45 years, totalizing 46.8% of all patients, the prevalence decreasing progressively with age. The mean age of patients was 45.7 ± 15 years, being lower for CD (44.09 ±14.9 years) than UC (46.02 ±15.1 years).

There were no statistically significant gender differences, with a slight predominance of CD in men (87 vs. 80) and UC in women (285 *vs.* 270), the total number being fairly equal (365 women and 375 men).

The number of patients diagnosed with IBD hospitalized more than one day in 2010, which was further taken into account

was 125.

In what regards the disease duration, as shown in the most hospitalized cases are newly diagnosed and those under 2 years from the onset, totalizing 47.5% of all cases (fig. 2).

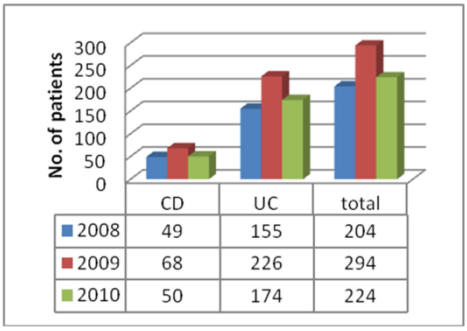

Fig. 1. Number of patients by year and type of disease.

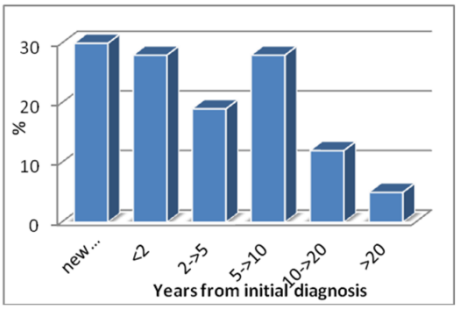

Fig. 2. Duration of the disease at evaluation.

Calculating the age at diagnosis it can be noticed that the maximal incidence in the analyzed cohort was in the age group 35-45 years (35%), followed by age group 25-35 years (27%). The mean age at onset among people with CD was 37.7 ± 13 years and in those with UC 42.8 ± 14 years.

Family history of IBD was reported in only one case (1.19%), whereas colon cancer was found in first-degree relatives in a higher proportion than in the general population (5.95%). Most subjects are non-smokers (57%) or former smokers (20%), the proportion of active smokers being of 23%.

Ulcerative colitis is most commonly (in almost half of cases) presented as left side colitis inflammation up to the splenic flexure) - 46.3%, followed by pancolitis (29.3%) and isolated rectal injury (24.4%). In Crohn's disease colonic involvement accounts for more than half of all cases, isolated ileal disease affecting just 14.3% of subjects. Almost 10% had lesions of the upper digestive tract and almost a quarter had perianal manifestations during evolution (fig. 3).

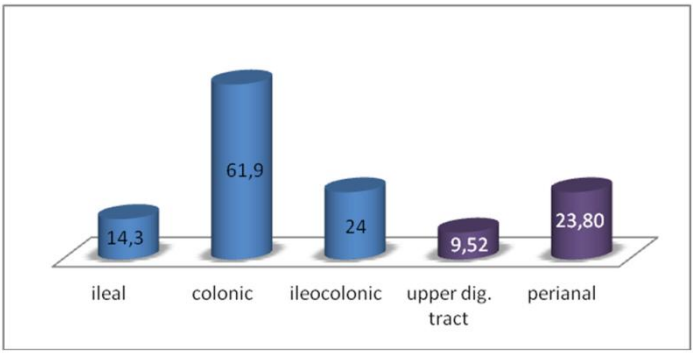

Fig. 3. Crohn's disease classification depending of localisation (%) .

Most cases of Crohn's disease were non-stricturing and non-penetrating (42%), followed by stricturing and penetrating forms (29%); 16.1% are stricturing and 12.9% are penetrating forms.

Mayo clinical UC score shows a balanced distribution of the three forms of severity (37% score 0-3, 33% score 4-6 and 27% score over 7). The calculation of Harvey-Bradshaw index highlights the prevalence of mild and moderate disease forms as follows: 21.4% score<5, 17.8% score 5-7, 50% score 8-16 and only 10.7% score over 16.

The most common extraintestinal manifestations were axial arthritis (ankylosing spondylitis and seronegative spondylarthropathies) in 13.6% of patients, followed by cholestatic syndrome evidenced by increased alkaline phosphatase and ocular manifestations - uveitis, scleritis and episcleritis (fig. 4). Overall, 35.25% of patients had at least one extraintestinal manifestation. Aphthous stomatitis has not been evaluated.

Colonoscopic evaluation was performed in 72.8% of patients. Over half of the subjects had a UC Mayo score of 2 (52.38%) and another quarter score 3 (26.19%). The analysis of simple endoscopic score of Crohn's disease shows mild to moderate forms predominance, with less than 10% being severe endoscopic forms: 28.5% score<3, 23.8% score 4-10, 38.09% score 11-19 and 9.52% score>20.

The correlation expressed by Pearson coefficient (r) of endoscopic Mayo score and SES-CD index with clinical scores and biological parameters of inflammation and P value is presented below (tab. I).

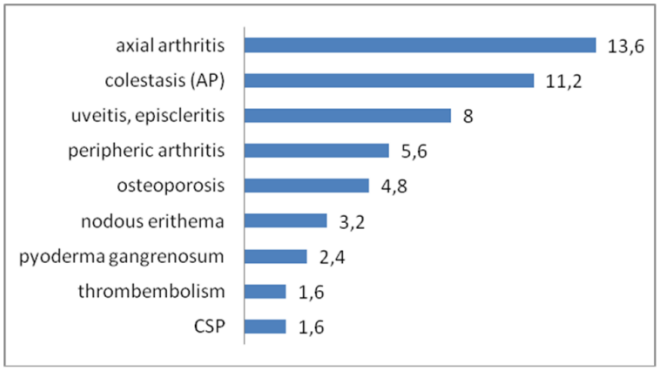

Fig. 4. Extraintestinal manifestations (%).

TABLE I

The correlation coefficient *r* of endoscopic Mayo score and SES-CD with various clinical and biological parameters and the corresponding *p* value

	Mayo endoscopic	P	SES-CD	P
Clinical score	0,727851	0	0,486445	0,109
WBC	0,522412	0,003	0,548403	0,101
ESR	0,562575	0,001	0,483462	0,125
Fibrinogen	0,695638	0,003	0,709565	0,049
CRP	0,711294	0,014	0,684553	0,134

We can notice that Mayo clinical score is a good indicator of the colorectal inflammation (strong correlation) compared to HBI score of Crohn's disease where the correlation with endoscopic activity is moderate. In both diseases, the correlation of the parameters of inflammation with endoscopic scores revealed that CRP and fibrinogen were superior to white blood cells and ESR.

DISCUSSION

One first aspect that stands out in all the 3 years studied is the small proportion of patients with Crohn's disease compared to UC cases (about 23%). This can be considered a particular aspect of the NE region of Romania, the prevalence ratio of CD for the neighboring regions being at least 30% in most cases (4,12). A possible explanation may be that Crohn's disease is under diagnosed, especially the forms located to the small bowel, given the technical and material difficulties of exploring this territory.

The age group distribution of our patients is similar to that reported for Europe, with the predominance of disease in young adults (up to 45 years). Most of the addressed cases are newly or recently diagnosed, probably because the optimal treatment for maintaining remission is reached after few years. Age of onset was higher among patients with UC, which is found in most epidemiological studies. Its average in the studied population is higher than in areas with a high incidence from northern Europe, being around 40 years (13). The second peak of incidence observed in older studies is not present in our cohort. The high age at onset may be a characteristic of the studied region.

Although there are no significant differences in prevalence according to patients' gender, we noticed a slight predominance of CD in men and UC in women, opposite to the trends from other regions (14).

Considering the limits of a retrospective study, we can conclude that extraintestinal manifestations are still in considerable proportion (about one third of the subjects) and in accordance with the literature (15). Osteoarticular manifestations are by far the most frequently encountered, and among them we mention the seronegative spondyloarthropathies and ankylosing spondylitis.

On a review of disease types, if for UC the relatively balanced distribution of the three forms with the predominance of left-side colitis is most often seen, in Crohn's disease we noticed an unusual predominance of colonic and ileo-colonic forms, the number of limited ileal forms being extremely small (14%). We believe that this may represent a feature of CD in this region, although insufficient exploration of the small bowel may contribute to the low proportion of pure ileal forms.

Even though the incidence and prevalence of CD are smaller than in neighboring regions (6), however the disease tends to be more aggressive, 48% of cases presenting an endoscopic score of moderate or severe injury, and the proportion of the stricturing and/or penetrating cases is more than a half (58%).

Another interesting aspect especially seen in UC by comparing the clinical and endoscopic scores is that although more than 70% of cases can be clinically classified as mild or moderate; in endoscopic examination 78% of subjects have Mayo endoscopic score of 2 or 3. Hence it can be concluded that UC is often undervalued when taking into account only the clinical picture, many less symptomatic patients

presenting at least moderate inflammation of the colonic mucosa.

From the biological parameters correlated with intestinal inflammation, C-reactive protein is superior to ESR and white blood cells in the evaluation of inflammation. Serum fibrinogen had surprisingly similar correlation numbers to CRP and thus significantly better than the ESR and WBC. Therefore, this often neglected and abandoned parameter in assessing systemic inflammation remains extremely valuable, especially where CRP determination is not available.

CONCLUSIONS

The main epidemiological features of inflammatory bowel diseases in NE region of Romania are the clear predominance of UC compared to Crohn's disease, older age at onset for both entities, higher tendency of CD to develop intestinal complications (stenosis, fistulas, perianal manifestations) and underestimation of intestinal inflammation by using only clinical and biological parameters. We propose a more careful and systematic exploration of the small bowel (videocapsule endoscopy, ileoscopy during colonoscopy, enteroscopy, CT, enterography) to diagnose Crohn's disease in case of subtle symptoms and in those already diagnosed with colonic forms and also the evaluation whenever possible of inflammation by endoscopic examination with biopsy or at least by the new non-invasive markers (calprotectin, lactoferrin).

NEWS

TREATMENT OF TB-HIV CO-INFECTION - A BIG CHALLENGE

Tuberculosis (TB) is a major public health problem worldwide. The association of TB with HIV infection induces a higher rate mortality caused by TB complications or by evolution towards AIDS. The treatment of patients TB-HIV co-infected is a big challenge. Even though the deferment in the initiation of antiretroviral treatment (ART) increased mortality, frequently the start of ART is delayed after completing TB therapy as a result of drug interactions between rifampicin and antiretroviral drugs, summation of side effects and low compliance to treatment with many drugs. By analyzing the several clinical trials, Naidoo and his collaborators showed that initiating ART earlier (within 2–4 weeks) after TB treatment initiation has induced reduction in mortality for the TB–HIV co-infected patients with advanced immunosuppression (CD4+ T-cell count <50 cells/μl). Mortality rate for the patients with baseline CD4+ T-cell counts of 50 cells/μl or higher was not influenced by the time of initiating ART in the course of TB treatment. The same analysis showed that an earlier ART initiation in immunosuppressed patients was associated with a higher risk for Immune Reconstitution Inflammatory Syndrome (IRIS). The same researchers showed that early ART initiation in the course of TB treatment for immunosuppressed patients will be based on compromise between increased survival and increased risk of IRIS (Naidoo K, Baxter C, Abdool Karim SS. When to start antiretroviral therapy during tuberculosis treatment? *Curr Opin Infect Dis*. 2013; 26: 35-42).

2. Discipline of Endocrinology

THE PLACE OF ULTRASOUND ASSISTED MEGALIPOSUCTION IN THE ROMANIAN OBESITY THERAPY DEDICATED PROGRAMS (Abstract): Obesity global epidemic and increasing number of super obese people requires a firm stand on the need for medical education of the general population and the need for aggressive therapeutic, but effective, methods, as its consequence is growth rate of comorbidities. The treatment of obesity is a combined treatment worldwide: lifestyle changes, medication and surgery. **The aim** of this article was 1) to highlight the obesity therapy in the world and the Romanian experience regarding bariatric surgery and the UAM (Ultrasound Assisted Megaliposuction) technique, 2) to underline the necessity of implementation of all new methods of obesity treatment in Romania and the possibilities to do that and 3) to determine the knowledge and the compliance of the Romanian obese patients regarding the new surgical obesity therapy technique. **Material and methods:** We conducted a personal single center survey on 30 obese persons in order to demonstrate the necessity of adjusting the obesity treatment in Romania to the European standards and the complete Romanian patient compliance regarding the new surgical obesity therapy technique. Responses to two questionnaires were evaluated. **Results**: Interpretation of the scores of the first questionnaire revealed a significant impairment of life quality. Evaluation of the second questionnaire results revealed that 60% of people studied had morbid obesity. These people may theoretically benefit from bariatric surgery techniques and UAM. **Conclusions**: The implementation of all new methods of obesity treatment in Romania, as an UE member state, is not an illusory idea, but a reality and it should be a matter of national interest. **Keywords**: OBESITY, ULTRASOUND ASSISTED LIPOSUCTION, MEGALIPOPLASTY.

Obesity is often neglected but is a very severe illness by morbid complications associated with it. Obesity global epidemic (GLOBesity) and increasing number of super obese people (BMI> 50 kg/m^2) requires a firm stand on the need for medical education of the general population and the need for aggressive therapeutic methods, but effective, as its consequence is the growth rate of comorbidities: cardiovascular (hypertension, cardiac overload, tachycardia), respiratory (breathing muscle wasting due to increased work needed for ventilation, sleep apnea syndrome), metabolic (glucose intolerance, diabetes, dyslipidemia), mobility (joint strain), endocrine (hormonal disorders) (1, 2) and premature death (3, 4) in this population.

Worldwide, 1 billion adults are overweight and 475 million are obese, leading

to more than 2.5 million deaths per year. In Europe, 260 million adults and 12 million children are overweight or obese. In Romania, 20% of men and 30% of women are obese. Over time were proposed several ways to treat obesity.

The aim of this study was: 1) to highlight the obesity therapy in the world and the Romanian experience regarding bariatric surgery and the UAM technique; 2) to underline the necessity of implementation of all new methods of obesity treatment in Romania and the possibilities to do that both technically, economically and in terms of housing and 3) to determine the knowledge and the compliance of the obese Romanian patients regarding the new surgical obesity therapy technique.

MATERIAL AND METHODS

We conducted a single survey center in Iaşi University Center, included 30 persons, 10 men and 20 women, aged between 16 and 60 years old (36.7+/-13.9) and a BMI between 30.1 and 55, 1 kg/m2 (38.6+/-6.3). The aim of this survey was to underline the necessity of implementation of all new methods of obesity treatment in Romania and to determine the patient compliance regarding the new surgical obesity therapy technique. Responses to two questionnaires were evaluated. This survey was approved by the Ethical Committee of the University of Medicine and Pharmacy "Grigore T. Popa" - Iasi and every person who participated in the survey has signed an informed consent.

The first questionnaire is a "quality of life" questionnaire, proposed by George Parkerson et al. in 1990 (5). The second questionnaire is a personal questionnaire that included 20 questions and try to emphasize knowledge of the studied persons about treatment methods of obesity and their compliance on UAM technique. The questionnaire was accompanied by an information sheet on bariatric surgery techniques and UAM.

For the rest of the data presented, the Internet was the source of information.

RESULTS AND DISCUSSION

Worldwide, the treatment of obesity is a combined treatment. Basically there are three major therapeutic principles: lifestyle changes, medication and surgery (bariatric and plastic surgery).

Surgery is the most effective way to combat morbid obesity after the U.S. National Institutes of Health (6). Surgery is dedicated to only selected cases, when other treatment methods have been exhausted: diet, sports, psychotherapy, anorexogenics, lipase inhibitor, behavioral therapy, therapy for possible endocrine disorders.

After bariatric surgery, the patient may benefit from a series of plastic surgery procedure to reshape the body: liposuction, dermolipectomy, brahioplasty, abdominoplasty.

UAM is a liposuction technique based on the use of ultrasonic energy, which allows the selective destruction or fat emulsification, which is then aspirated. With this method the blood loss are minimal (7,8) and the amount of lipoaspirate that can be eliminated in a single session can reach up to 20 liters. For this reason UAM can be used in the treatment of obesity. Unlike traditional liposuction, UAM selectively destroys only target adiposity and spares support structures of the skin and dermis, such as vessels, nerves, collagen matrix and elastic fibers, thereby preserving the elasticity of treated areas (9).

It has been hypothesized that liposuction should not only have a remodeling role but also a functional one, removal of large

quantities of fat lead to increased lipase activity, leading through a feedback mechanism, to a continuous reduction in body weight, linked to inhibition of hunger center (10, 11, 12). For this reason, liposuction is performed not only for aesthetic reasons but also for therapeutic purposes to improve the quality of life of obese patients.

UAM can be practiced in combination with bariatric surgery in the treatment of morbid obesity, but it may represent a reliable alternative to this.

In Romania, there are about 300,000 obese patients who should benefit from such interventions. Of these, only 4,500 were operated in the last 20 years, over 2,500 by Dr. Catalin Copaescu and his team, at BariXL Center, the only center of excellence in the treatment of obesity and metabolic diseases in Romania, center accredited by specialized forums in Europe and the United States (IFSO- EC).

In Romania, laparoscopic gastric bypass, gastric banding and gastric sleeve procedures are performed in Bucharest, Timisoara, Cluj Napoca, Târgu Mures. In Romania, the first laparoscopic gastric bypass surgery was performed in 2002 (13, 14). Since then, 170 operations of this type were performed. This experience is a priority in Romania. The experience of Romanian surgeons in the laparoscopic treatment of obesity approaches 1,000 patients, thus constituting one of the most important experiences in the Balkans. However, it cannot be said the same about their experience in terms of UAM technique. There are no publications concerning the application of this method in Romania.

Technically and in terms of housing, UAM can be introduced in the Romanian obesity therapy dedicated programs in centers where there is an interdisciplinary group involved in the study and treatment of obesity (table I) and only after surgeons were familiarized and trained in performing this surgical techniques, in order to minimize intraoperative and postoperative complications. The learning curve of this technique is long (15,16), it involves a minimum of 30 patients and it requires careful attention to detail in terms of volume of tumescent solution infiltrated and ultrasound aspiration time (17).

TABLE I

Interdisciplinary group involved in the study and treatment of obesity

NUTRITION AND METABOLIC DISEASES	GENERAL SURGERY	PLASTIC AND RECONSTRUCTIVE SURGERY	PSYCHIATRY PSYCHOLOGY
Bariatric Medicine	Bariatric Surgery	Body reshaping surgical techniques	Treatment of eating disorders
Control of Diabetes		U.A.M.	

From an economic perspective, in the year 2000 it was published a comparative evaluation of systemic effects, efficacy and cost for SAL, PAL and UAM (16). Cost analysis (table II) showed that UAM is the most expensive technique. The choice of the ideal technique depends always on the surgeon. Thus, UAM is the technique preferred by surgeons for patients with morbid obesity, being the only method that allows liposuction of a large amount of adipose tissue in one surgical session, with minimal blood loss (7,8). UAM equipment is indispensable for the complex treatment of obesity and it should be found in all specialized centers.

Nowadays, the public health sector in Romania is going through a difficult period. Not the same can be said about private medical services, which are more present than ever.

The number of private hospitals, increased from 12 in 2006 to 84 in 2012, are able to raise to the necessary UAM application requirements in the treatment of obesity. Thus, the implementation of all new methods of obesity treatment in Romania, as an UE member state, is not an illusory idea, but a reality and it should be a matter of national interest and a priority of the Ministry of Health.

	Cost (units)		
	SAL	**PAL**	**UAL**
Hospitalization	1	1	1
Surgery room	1	0.75	1.25
Equipment	0.06	1	6
Total	2.06	2.75	8.25

Our survey was approved by the Ethical Committee of the University of Medicine and Pharmacy "Grigore T. Popa" - Iasi and every person who participated in the survey has signed an informed consent.

Interpretation of the scores of the 10 scales of the *Duke Health Profile* questionnaire revealed a significant impairment of life quality both physically (43.3+/-24.4), mentally (55.3+/-40.1) and from the socio-professional point of view (51.6+/-30.5). Most people have a real perception (45+/-37.9) of their general poor health condition (50.06+/-25.6). For this reason we notice a decrease in the self-esteem score (53.3+/-35.7) and depression-anxiety installation (Duke-Ad Score 44.4+/-32.05). Duke Health Profile questionnaire assessment results emphasized once again that obesity is a disease often overlooked due to the lack of pain (Pain Score 38.3+/-33.9) but very severe and associated with morbid complications (Disability Score 60+/-33.2). Resolution of co-morbidities and regaining of self-esteem would improve dramatically the quality of life.

By evaluating the responses to the *20 questions of the personal questionnaire*, we reached the following results: 30% of people had a I^{st} grade obesity (BMI 30.1 -33.8 kg/m2); 30% of people had a IInd grade obesity (BMI 35.6 -38.5 kg/m^2) of which 20% of people show associated comorbidities and 40% of people had IIIrd grade obesity (BMI> 40.1 to 55.1 kg/m^2). In conclusion 60% of people had morbid obesity.

In our study, *40% of people, 30% with I^{st} grade obesity and 10% with IInd grade obesity but without associated comorbidities*, can benefit from medical treatment and only for inefficiency of this therapy after 1 year, we can discuss a UAM technique, not having bariatric surgery indications in these cases. Only half of them (1 man and 5 women) had medical therapy instituted: 1 man and 1 woman had diet associated with sports and drug therapy and 4 women had diet associated with sports and psychotherapy. Although all 5 young people (2 men and 3 women) aged between 16 and 19 years old had a form of depression, only 2 women of 16 and 18 years old have received medical psychotherapy. The medical treatment was of minimum one yearin 4 cases and of 6 months in 2 cases. Its efficiency could be observed only in 3 cases of the 4 who benefited from therapy more than one year. The patient who received this therapy for one year and to whom it proved ineffective, can benefit from UAM. The other two cases should continue therapy for at least one year and

for the 6 cases who remained untreated, it can be established a complex medical therapy for at least 1 year. In case of its inefficiency after one year (30% of people), UAM may be considered for patients without contraindications.

From all the patients, *60% of people with morbid obesity, 20% with IInd grade obesity and associated comorbidities and 40% with IIIrd grade obesity*, can theoretical benefit of bariatric surgery techniques and UAM as conservative therapeutic methods (diet, exercise, medications) are effective in patients who do not have severe forms of obesity (BMI < 35 kg/m^2). In the case of morbid obesity results are poor, but conservative treatment methods must be applied for at least one year before surgical techniques. Obesity surgery is considered today the most effective treatment for morbid obesity. Only 30% of people with morbid obesity had indications for bariatric surgery and 16.6% for UAM. Contraindications were represented by depression (23.3%), varices (10%), inguinal hernia (6.6%), and weight > 140 kg without weight loss diet (6.6%), effective gastric banding (3.3%), diagnosis of less than 5 years (3.3%).

In conclusion, assessment of the second questionnaire results revealed that in the moment of the study only 30% of people with morbid obesity had indications for bariatric surgery and 16.6% for UAM. In case of inefficiency of the one year medical therapy in the case of the 30% people with no morbid obesity, 46.6% had indications for UAM.

With regard to information held by 30 people, only 36.6% (age 16-29) had summary information about bariatric surgery and only 13.3% (age 25-36) about UAM. The source of information was represented by the physician in 16.6% cases and by Internet in 33.3% cases. Given this situation, people compliance on this technique was very low 16.6%. The people compliance on this technique has increased 3.6 times after reading the information sheet attached to the questionnaire concerned.

All patients have shown interest in being included in a therapeutic program for obese patients, including: diet, sports, psychotherapy, bariatric surgery, UAM, body shaping and other techniques.

It should be noted that our survey, being accomplished in a single center, can be only a mere guide, thus it is necessary a multicenter study to define the result.

CONCLUSIONS

Obesity is a serious medical condition. Co-morbidities related to obesity are responsible for decreased life expectancy by nine years to women and by 12 years to men. In Romania, one of two people is overweight and one of four is obese.

Treatment of obesity should be a combined treatment: diet, sports, psychotherapy, drug therapy, bariatric and plastic surgery. Surgery is the most appropriate therapeutic option for patients with morbid obesity.

UAM has metabolic effects and significant morphological effects, improving quality of life of patients who maintained a constant body weight (12). UAM can be practiced both in combination with bariatric surgery in the treatment of morbid obesity, but it may represent a reliable alternative to this, when patients refuse it. In addition, UAM represents an attractive alternative for patients with BMI 30-40 kg/m^2 and surgical recommendation, who are not candidates for bariatric surgery and are unresponsive to other forms of therapy. UAM is also a solution in the case of juvenile obesity (young people up to 18 years old, not having a bariatric surgery indica-

tion, for which other treatment methods have failed).

The experience of Romanian surgeons in the laparoscopic treatment of obesity is one of the most important experiences in the Balkans, but there are no publications concerning the application of UAM method in Romania, although it has become in Europe and the United States one of the basic techniques of body reshaping methods arsenal since 2001.

For the UAM technique to become a reality also for obese patients in Romania and for obese patients to be included in a specific therapeutic program, several conditions must be taken in consideration:

- creation of centers adequately equipped in the existing private hospitals, with an interdisciplinary group involved in the study and treatment of obesity (nutritionist, general surgeon, plastic surgeon, anesthesiologist, psychologist);

- organization of UAM learning technique trainings for surgeons;

- creation of a grant program for patients with indications for operation, given the precarious pecuniary situation of the population;

- organization of information programs both for population and for family physicians (brochures, radio, TV, internet, conferences, symposia, etc.).

2. Clinical Hospital of Psychiatry "Socola", Iaşi.

STATISTICAL ANALYSIS OF SUICIDE CHARACTERISTICS IN IASI COUNTY (Abstract): A prospective study intended for statistic analysis of suicide events occurring in 2004-2009 period, in Iasi County, was performed. Specific data emerged from the conventional investigation, focusing on the sex, age, seasonality, marital condition, occupation status, blood alcohol concentration, religion adherence, and previous suicide attempts of the persons who committed the lethal self-aggression. The results showed a males: females (M:F) ratio of 4.13:1, central tendency to suicide towards the 46 years, a mean age of the self-murderers series of 45 years, while the most frequent age was 49 years. The interquartile range expanded from 33 to 56 years. The rural: urban (R: U) ratio was 1.38:1, whereas a statistically-significant seasonal variation was found in villages. Suicide events occurred more frequently around the Easter and Christmas, whereas the orthodox Christian believers seemed to suicide more than Catholics. Additionally, a correlated analysis, based essentially on data provided by the local Institute of Legal Medicine and Psychiatry Hospital, offered a comprehensive understanding of the mental state of the self-murderers and their psychiatric profile. **Key words**: SUICIDE, SEASONALITY, ALCOHOL, MENTAL DISEASES, RELIGION

The human history knows several forms of deliberate killing, the main types focusing on the well-known human-animal linkage, the relation of a person with his fellow(s), or the relationship of a person with himself. Not exhaustively, the first was named food-motivated act, defending or entertainment, the following murder or self-defense, while the third as suicide or martyrdom. However, the above inventory can modify according to the social, moral, ethical, religious and legal values or standards taken into account.

All the above exposed killing types are important and challenging from the scientific standpoint, being continuously investigated to make clear their causes, level of significance, frequency, and consequences. However, of all killing forms, suicide is the most investigated phenomenon. The rationale sustaining the high received interest comes from the fact that it is a complex act, with numerous influences, including personal (biological, psychological, psychiatric), social, economic, political and cultural components (1-3).

Consequently, suicide-related up-to-date studies are needed to periodically be performed to investigate as much as possible the previous "inner state" of a population to make correct decisions on the appropriate prophylactic means to be consid-

ered for suicide prevention.

In this work, we focus on a deliberate killing involving suicide-related phenomena. The statistic analysis over a local population was performed in order to evaluate a series of variables such as sex, age, marital status, occupation category, seasonality, religious adherence etc. in order to well establish their influence on the suicidal act and to be further used to make correct decisions on the suitable prophylactic methods. Apart from the above described analyzed variables, the study sought also for a comparison between rational and pathologic suicide to underline possible correlations between the mental healthiness, inner psychological state and the lethal act.

The analysis is a prospective one and is focused on the suicidal events performed in Iasi County, a representative region of the North-East part of Romania, comprising a population of 816 910 persons (according to the 2002 census) and a relatively homogenous religion-related distribution (4).

MATERIAL AND METHODS

This work has taken into account a six-year period, i.e. 2004-2009, and comprised 679 suicidal events that were issues of the local Institute of Legal Medicine, Clinical Hospital of Psychiatry "Socola", and Register Office of Iasi County, Romania. A correlated analysis was needed because despite the Romanian legislation imposes forensic autopsy of the self-murderers by which important medical information focused on the death's causes are obtained, the requirements to clearly establish the psychically integrity of the self-murder in the moment he acted as such remain unfulfilled.

The statistical analysis was based on descriptive parameters like median, mean, mode values, and standard deviation interquartile range. The frequencies were analyzed by using the Pearson's chi-square test of "goodness to fit", with an imposed 0.05 limit of probability.

RESULTS

During the six years studied, 17 154 suicides were committed in Romania, among them 679 cases (3.96 %) occurring in Iasi County, in a population that represents 3.77 % from the Romanians. The annual average suicide rate, calculated for the six years, was 13.85 per 100,000. Suicide distribution, on the sex, rural and urban media, and age categories, is displayed below (tab. I).

TABLE I

Annual average suicide rate on the sex, area, and age category

Sex / Area / Age category	Number of cases (six years)	Total inhabitants (Iasi County)	Annual suicide rate (to 100,000 inhabitants)
Male	540	401,516	22.41
Female	139	415,394	5.58
Rural	410	429,124	15.92
Urban	269	387,786	11.56
< 20 years	50	235,179	3.54
20 – 39 years	200	261,744	12.73
40 - 59 years	301	183,794	27.29
> 59 years	128	136,193	15.66

As table I points out, the most encountered suicide cases were found to males (M:F = 4.13:1), and emerged more from the rural area (R:U suicide rate ≈ 1.38:1), while the most affected population segment was 40 - 59 years.

Absolute number of the self-murderers has increased yearly, in spite of apparent Gaussian distribution of the urban suicide events (fig. 1).

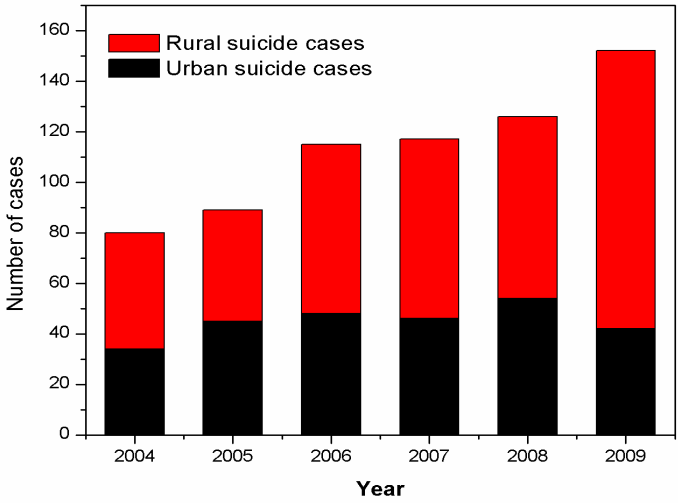

Fig. 1. Year-dependent distribution of suicide events

According to Table II, the central tendency to suicide was towards the 46 years (median parameter), mean age of the self-murderers series was 45 years, while the most frequent age was 49 years (mode parameter). The middle fifty, i.e. interquartile range, expanded from 33 to 56 years. As it can also be observed, men suicide slightly earlier during their life as compared to women, whereas the age difference was of only 1-2 years.

The number of season-distributed self-murderers and statistical significance related to urban and rural media are summarized in Table III. Season variation is significant only in rural medium where the highest value is attained in autumn period (29 %), whereas the occurrence of such events is less observed in winter (17 %). However, for the total cases, the highest value of suicide events moved to summer (28.57 %).

TABLE II

Age descriptive parameters

Age parameter	Global (years)	Male (years)	Female (years)
Median	46	46	48
Mean	45	45	46
Mode	49	48	49
Interquartile range (Q_3-Q_1)	56-33	55-34	60-31

TABLE III
Seasonality of suicide events and statistical significance

Season	Total			Urban			Rural	
	Observed	Expected		Observed	Expected		Observed	Expected
Spring	178	170		70	68		108	102
Summer	194	170		81	68		113	102
Autumn	182	170		63	68		119	102
Winter	125	170		55	68		70	102
p-value	$p < 0.001$			$p = 0.14$			$p < 0.01$	

As regarding the family status of the persons who committed suicide, from the 679 cases investigated, marital status was found for only 385. Among them, 200 persons were married, 139 un-married, 22 widowers, whilst 11 cases were noted as concubinage.

We also analyzed some data related to alcohol intake at the moment the self-murderers committed the lethal act. Accordingly, from the 679 suicide cases, 288 persons consumed alcohol (42.42 %), 267 being men and 21 women. Therefore, taking into account all cases, i.e. 540 men and 139 women, 49.44 % out of men and 15.11 % out of women consumed alcohol before suicide. As regarding the blood alcohol level, 78 % self-murderers from the 288 cases had a blood alcohol concentration higher than 1 g ‰.

Due to the underreporting of suicidal deaths in the registry system, the socio-economic status was available just for 358 persons, 23.46 % being employed, 32.69 % retired, 32.4 % unemployed or without occupation, and 11.45 % pupils or students.

From the education standpoint, data for 365 cases were available. The analysis showed 9.04 % persons with university education, 66.57 % with high school education, 23.83 with primary education, and 0.55 % without school instruction. However, these data were not complete and therefore could not be compared with their corresponding items in the population of Iasi County to draw out relevant conclusions.

Referred to all studied cases, a medical record of mental illness was found for 189 self-murderers (27.83 %), 80 persons being registered once, 32 twice, and 14 were found with 3 records summing 18.55 % from all suicide cases. The most involved mental diseases were depression (35.45 %), alcoholism (31.74 %), schizophrenia (6.88 %) and dementia (5.29 %).

On the other hand, we found 92 cases (13.55 %) of previous suicide attempts, but the exact number of attempts was generally found to be registered only for less than 3 attempts, the others being noted as "multiple". Referred to their counterparts, i.e. 540 men and 139 women, 12.22 % (66 cases) occurred for men, whereas women represented 18.7 % (26 cases). In addition, from all the 92 cases, 46 self-murderers (50 %) had a medical record of mental illness at "Socola" Hospital.

We investigated as well the religious adherence of the self-murderers in a Romanian region where orthodox Christians are majorities (92.55 %) whereas the second important religious minority is Catholic (4.94 %). From the 354 cases whose religious confession was found, 341 (96.32 %) belonged to Orthodox Church, 11 (3.1 %) to Catholic Church and 2 (0.56 %) were non-religious. Mirrored in their corre-

sponding items in the total population of Iasi County, the obtained data showed a slightly increased suicide rate of the Orthodox Church's believers.

We observed that close to the main Christian holydays, i.e. Easter and Christmas, the suicide incidence increased. Thus, taking for analysis one month (2 weeks around Easter day plus 2 weeks around Christmas day) per year, 69 self-murderers were recorded for the entire analyzed period. Therefore, for the cumulated six months, the monthly suicide rate was 11.5. Comparatively, for all the six years, monthly suicide rate was 9.43.

DISCUSSION

For our target population, the suicide rates are higher in villages, with a peak in autumn and a gap in winter. It is somehow a contradictory result if a prophylactic role of the work is considered. Since the work activities in rural areas are highly increased in autumn and at low level in winter, in order to comprehend the results of the study we should give credit to other explanations such as season-related physiological alterations. Indeed, it is reported that sunlight, for instance, with higher activity in spring, summer and autumn, through interactions with brain serotonin, is able to trigger increased impulsivity and suicidal behaviors (5-8). In other words, winter acts as a prophylactic factor by providing a sort of "hibernation" state leading to the amelioration of the inner psychological pain by "restarting" the person's emotional sphere towards a new possible successful beginning in the next year.

Alcohol intake is a frequent precursor to suicide, and alcoholics are at a high risk. Generally, studies on suicide showed that alcoholics account for 20 % - 40 % of all suicide events (9). Therefore, the alcohol-related data emerged from our study fitted fairly well with specific literature data, taking into account a value of 42.42 % obtained for both alcoholics and non-alcoholics self-murderers that consumed alcohol just before suicide event. To alcoholics, the alcohol, by itself, is not the suicide's cause, but the social and familial tensions, disruptions, isolation, and associated depression, emerging due to alcohol long-term misuse, are the real causes of the alcohol-influenced suicide. Also, the relatively high blood alcohol levels (> 1 g/l) can be correlated with their need to fight the inner fear and maybe to stop conscience accusing them against consecutive consequences of this act on, for examples, family, friends etc.

Only 23.46 % of investigated cases were represented by the employed people, pointing out the protective role of the work. In this context, it is possible that an indirect cause for the pupils/students suicide to emerge also from family work-related economical problems.

We also observed that women are more susceptible to suicide attempts as compared to men, the women-to-men suicide attempts ratio being 1.5: 1. This result follows the profile of the general trend of the globally encountered behavior of suicide attempts. However, 50 % of persons with suicide attempts were observed to have at least one psychiatric recording, emphasizing how important is the proper mental state in limit conditions.

Focusing on the appropriate medical recordings of the local psychiatric hospital, an increased percentage (about 30%) of self-murderers had psychic deficiencies. For these patients, psychiatric healthcare seemed to be insufficient to solve only by

itself the most profound problems. Moreover, the psychiatry-suicide relation takes out collateral questions. For instance, what if another important part of the self-murderers suffered psychically and no psychiatric recording was made throughout their life? Or, equivalently, how many self-murderers, viewed mentally as healthy people, had been suffered actually by hidden minor-to-medium mental problems or, at least, had been combined a minor mental illness with a medium-to-high psychological problem ? Furthermore, could the suicide thoughts be truly encountered also to important percentages of normal people? Is there an equilibrium barrier between life and death desire so fragile that can break down for many normal people? We assume there are few normal people able to recognize the presence of such thoughts because of the increased risk to degrade their social, professional, and familial image.

Finally, the increased suicide rates around important Christian holidays can be explained by considering an exacerbation of certain feelings triggered by the meaning of these special days where sole people, predisposed generally to depression, become more vulnerable to suicide. Also, the connection of the suicide date with central Christian holidays can be intended for the amplification of an accusing message against those considered guilty for their death.

CONCLUSIONS

Applied to Iasi County, our study showed an average suicide rate of 13.85/100,000. Also, the statistical analysis pointed out that males suicide much more than females (M:F = 4.13:1), whereas cases emerged from rural regions are more frequent as compared with urban areas (R:U suicide rate ≈ 1.38:1).

The central tendency to suicide was towards the 46 years, mean age of the self-murderers was 45 years, while the most frequent age was 49 years.

The study underlined that two groups present high suicide risk: men and middle-aged population.

Alcohol, season, period of day, and main Christian holydays were shown to trigger the suicide behavior. Moreover, the analyzed suicide events were shown to comprise important percentages of psychiatry-related cases, mental problems playing a decisive role to view suicide as an escaping way, possible from the "prison" of psychic torture.

The suicide prophylaxis should be more focused on the higher-risk population groups and should supplementary address to the risk factors affecting all groups of self-murderers. Probably, cooperation with local Churches to prevent this hardly predictable phenomenon and, further on, to assist the affected families would be highly helpful.

NEWS

NEW TOOLS FOR FIGHT THE FLU

A new research was developing for construction of computer-designed proteins to fight the flu. The researchers have suggested that these proteins found in nature, but that do not normally bind the flu, can be constructed via computer modelling to act as broad-spectrum antiviral agents against a variety of flu virus strains.Hemagglutinin enables the virus to attach to the surface of cells lining the airways. After virus penetration into cells, under the influence of acid intracellular pH, the hemagglutinin change shape and thus allows initiating viral RNA replication. By binding the hemagglutinin in a very specific orientation, like a key into a lock, the computer-designed proteins block his shape change and viral invasion of cells. These inhibitor proteins bind to all types of the Group I Hemagglutinin, a group that includes H1, the pandemic H2 and avian H5 strains.The scientists could use protein interface design to generate a variety of proteins that would block pathogen-host cell interaction.

FUNCTIONAL STATUS OF CHRONIC RENAL REPLACEMENT THERAPY IN ELDERLY PATIENTS – COMPARISON BETWEEN HEMODIALYSIS AND PERITONEAL DIALYSIS (Abstract): Nowadays, nephrologists are confronted with an increasing number of elderly patients diagnosed with end-stage renal disease (ESRD) in need of dialysis. The benefits of renal replacement therapy are uncertain in this group of patients. Most studies show that the quality of life and survival of elderly dialyzed patients are worse than in younger patients because of multiple comorbidities. Functional status is an important aspect of the quality of life, a strong predictor of survival and a determinant of the health care systems costs. **Method:** In the present research, we compare the change in the functional status – appreciated with the MDS-ADL score – in a cohort of hemodialyzed versus peritoneal dialyzed elderly patients (>65 years) during a period of 3 years after starting dialysis treatment. **Results:** At the time of initiating dialysis, the median minimum data set of activities of daily living (MDS-ADL) score in hemodialysis (HD) elderly patients was 4.04 and in continuous ambulatory peritoneal dialysis (CAPD) group was 6.27 (the median MDS-ADL score at the moment of starting dialysis was statistically significant higher in peritoneal group than in hemodialysis elderly group). **Conclusions:** The results conclude that elderly treated with peritoneal dialysis have a better evolution of functional status than hemodialyzed elderly patients do. **Key words:** END-STAGE RENAL DISEASE, ELDERLY, HEMODIALYSIS, PERITONEAL DIALYSIS, FUNCTIONAL STATUS, MDS-ADL SCORE.

In the last two decades, an increasing number of elderly patients diagnosed with end-stage renal disease (ESRD) have started dialysis (1,2). In most of developed countries, more than 40% of the patients initiating dialysis are aged over 65 years old (3). In 1995, in Europe, 52% of the patients who begun dialysis were more than 60 years old (4).

In 2008, data from USRDS (United States Renal Data System) shows that in the USA – the country with the highest incidence of CKD (chronic kidney disease) – the median age of dialysed patients was

64.4 years (5). Comparative to 1998 (when elderly represented 47% from all dialysed patients (5)), the raise of ESRD incidence in persons >65 years was of 11%, comparative with 2.4% in 20 – 44 years age-group and 6.1% in 45 – 64 years age-group (5).

The benefits of dialysis in elderly adults are uncertain (6,7,8). Mortality in the first year after the initiation of dialysis exceeds 35% among patients older than 70 years and exceeds 50% among patients older than 80 years (8). Clinical trials comparing survival of elderly uremic patients treated with dialysis versus conservative management show that the prognostic depends less of the patient's age, but more of the number of comorbidities and early referral to a nephrologist (1,6,7,9). Most of these studies concluded that, in the presence of multiple comorbidities, survival is identical in both types of treatment (1,9).

The optimal modality of dialysis in elderly is a matter of debate, as well (7). Most studies comparing hemodialysis (HD) and peritoneal dialysis (PD) in elderly – in terms of quality of life or survival – failed to demonstrate the superiority of one therapy versus the other (3,8).

Functional status – the ability to perform activities such as walking, bathing, dressing, getting out of bed, and using the toilet – is an important aspect of the quality of life in elderly patients, a strong predictor of survival and a determinant of the health care system costs (6,8,9,10). In our clinical research, we compare the change in functional status – appreciated with the MDS-ADL score – in a cohort of hemodialysed versus peritoneal dialysed elderly patients (>65 years) during a period of 3 years after starting renal replacement therapy (RRT). Limited data regarding this comparison is present in the literature, most studies being performed in nursing homes. As in Romania, nursing homes are practically absent and the management of elderly patient needs family collaboration with the nephrologist, we consider useful to evaluate the change in functional status in both types of dialysis therapy in order to appreciate the optimal modality of treatment.

MATERIALS AND METHOD

During January 2006 – December 2007, nondiabetic patients diagnosed with ESRD who initiated dialysis and were > 65 years old at the time of initiation were included in the study. The follow-up period was for 3 years from the moment of the dialysis initiation and the study ended in December 2010. The patients were classified as HD or PD treated patients only after 3 month of stable dialysis therapy.

Functional status of the patients have been measured at 6-months interval using **MDS-ADL** score (**M**inimum **D**ata **S**et of **A**ctivities of **D**aily **L**iving) (tab. I). Originally developed by *Sidney Katz* in 1963, the Index of Independence of Activities of Daily Living, or Index of ADL, is one of the oldest and most widely used health measures (11). Over the years, *Katz*'s system has been modified and expanded (2).

Each ADL item has six possible categories of response representing observations made by a trained clinical professional over an assessment period of seven days. Assessments based on observed rather than self-reported physical function were considered more reliable.

The categories of response for the MDS-ADL self-performance scores were ranged from '0' (total independence) to '4' (total dependence). The MDS Long Form ADL scale is a sum of the responses to all the seven individual ADL items and has a

range from '0' to '28' (higher scores indicating a greater dependence). The score modality in MDS-ADL questionnaire is: **0** – total independence or no or little help with an activity; **1** – supervision provided 3 or more times during last 7 days; **2** – limited assistance by another person (medical staff, family member) with the patient highly involved in activity; **3** – extensive assistance by another person (medical staff, family member) with the patient performing part of the activity; **4** – total dependence and full participation of another person (medical staff, family member) in activity during the entire 7 days. Evaluation of MDS-ADL was performed at the moment of dialysis initiation and then at 12-months intervals. Statistic validation of data was performed using rank *Mann – Whitney, Z and T tests*.

TABLE I
The items included in the MDS-ADL score

ITEM	DESCRIPTION
Eating	How the patient eats and drinks, including other means of intake of nourishments (tube feeding, gastrostomy).
Dressing	How the patient puts on, fastens, takes off all items of street clothing.
Locomotion	This includes how the patients move between locations in their room and corridor outside their room.
Personal hygiene	This relates to how personal hygiene is maintained, including combing hair, brushing teeth, washing and drying face and hands; baths and showers are excluded from this item.
Bed mobility	This includes how a patient moves and turns his body position while in bed.
Transfer	This includes how a patient moves between surfaces such as a bed and chair.
Toilet use	How a patient uses a toilet, commode, bedpan or urinal and transfer on and off the toilet.

RESULTS

Between January 2006-December 2007, 65 elderly ESRD patients have begun dialysis therapy: 18 on CAPD and 47 on HD. From all new patients who started CAPD in the mentioned period, elderly represented 47.36%. The median age was 73.16 years. Ischemic nephropathy was the main primary renal diseases (66.7%); in 6 patients it was associated with other cause of renal failure. From all new hemodialyzed patients, elderly represented 19.18%. The median age was 70.53 years. The main causes of renal failure were ischemic nephropathy (29.78%) and tubule-interstitial chronic nephropathy (29.78%). ESRD etiology was mixed in 6 patients. At the time of initiating dialysis, the median MDS-ADL score in HD elderly patients was 4.04 (fig.1): 10 patients (21.27%) had a MDS-ADL score ≥ 7, needing extensive assistance from a family member in order to perform usual daily living activities; 20 patients (42.55%) had a MDS-ADL score between 1-7; 17 patients (36.17%) had a MDS-ADL score 0, being completely able

to perform daily activities with no help or minimal help from another person. In CAPD (continuous ambulatory peritoneal dialysis) group, at the time of initiating dialysis, the median MDS-ADL score was 6.27 (fig. 1): 7 patients (38.88%) had MDS-ADL score ≥ 7; 7 patients (38.88%) had MDS-ADL score between 1-7; 4 patients (22.22%) had MDS-ADL score 0.

After starting dialysis, evaluation of MDS-ADL score was performed at 6 months intervals. Obvious, as the time passed, the number of patients in which the MDS-ADL score was evaluated changed because of death reported in both groups (fig.2, fig.3).

In the HD group, the median MDS-ADL score sharply increased in the first 6 months. After that, we recorded a stability of the score until the end of the first year. In the second year and in the third year, the MDS-ADL score increased progressively until the end of the study (tab. II). The raised of the score was with 2.22 points. As the evaluation of MDS-ADL score was performed only in patients who remained alive and presuming that the patients with the highest scores died until the end of the study, the 2.22 points increase of the score seems important.

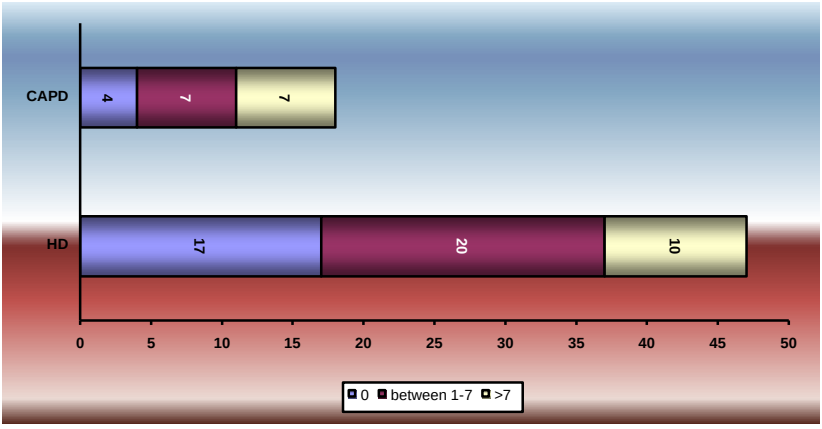

Fig. 1. MDS-ADL score at the time of dialysis initiation in the two groups of elderly patients

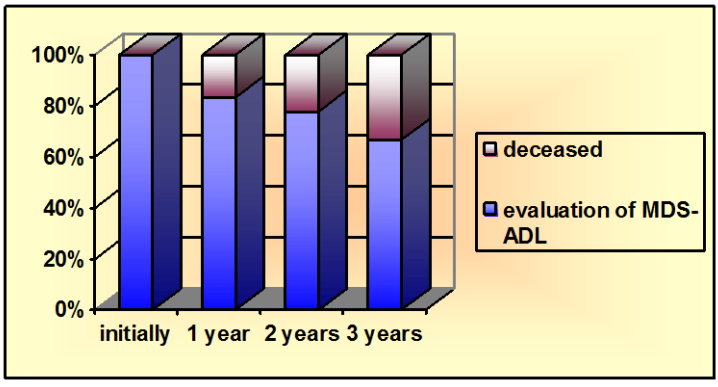

Fig. 2. Number of CAPD patients in which the MDS-ADL questionnaire was performed

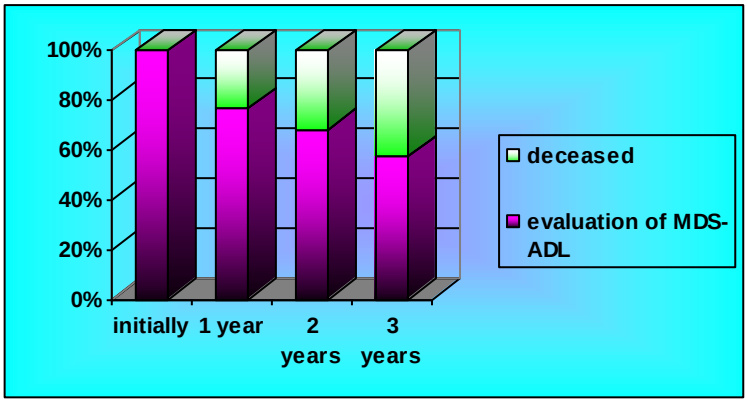

Fig. 3. Number of HD patients in which the MDS-ADL questionnaire was performed

TABLE II

Evolution of MDS-ADL score in hemodialyzed elderly group

ADL score	0	6 months	12 months	18 months	24 months	30 months	36 months
0	17	12	12	10	9	9	9
1-7	20	14	16	15	15	13	11
> 7	10	11	8	9	8	8	7
Deaths	0	10	11	13	15	17	20
Median ADL score	**4.04**	**4.40**	**4.27**	**5.32**	**4.97**	**6.16**	**6.26**

In peritoneal dialysis group, the median MDS-ADL score decrease significantly in the first 18 months from the dialysis initiation, proving a substantial improvement of the functional status. After that, the median MDS-ADL score increased, but more slowly than in hemodialysis elderly group (tab. III).

TABLE III

Evolution of MDS-ADL score in peritoneal dialysis elderly group

ADL score	0	6 months	12 months	18 months	24 months	30 months	36 months
0	4	5	5	5	5	5	5
1-7	7	6	6	6	5	4	3
> 7	7	5	4	3	4	4	4
Deaths	0	2	3	4	4	5	6
Median ADL score	**6.27**	**3.75**	**3.40**	**3**	**3.14**	**3.46**	**3.83**

DISCUSSION

When dialysis was started, the proportion of elderly patients completely independent (score 0) or partially dependent on help from another person (score 1-7) was significantly lower in peritoneal dialysis

group (fig.4) – *T-test*.

The median MDS-ADL score at the moment of starting dialysis was statistically significant higher in peritoneal group than in hemodialysis elderly group (*Mann-Whitney rank test*) (fig. 5). These results concluded that elderly patients with debilitating comorbidities that reduce the ability to perform daily minimum activities were preferentially oriented to peritoneal dialysis. Peritoneal dialysis, a procedure that is considered more "physiological" than hemodialysis was chosen to protect the patients from the potential risks of hemodialysis. As in Romania, homedialysis or nursing homes (where a specialized person performs dialysis) are not available as in developed countries. The choice of hemodialysis in patients with severe comorbidities becomes an important problem even if we see it only from the point of view of patient transportation to and from the hemodialysis center.

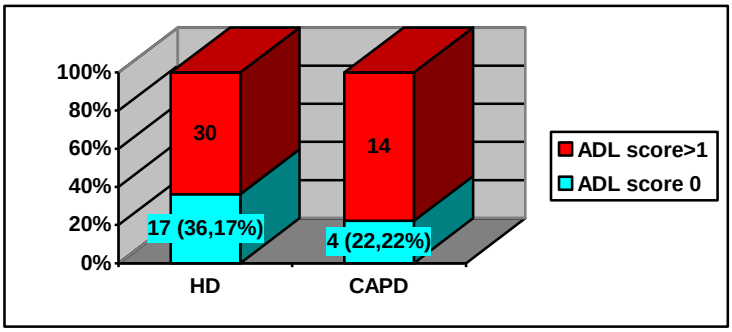

Fig. 4. Percent of the patients with preserved independence in performing daily activities (MDS-ADL score zero)

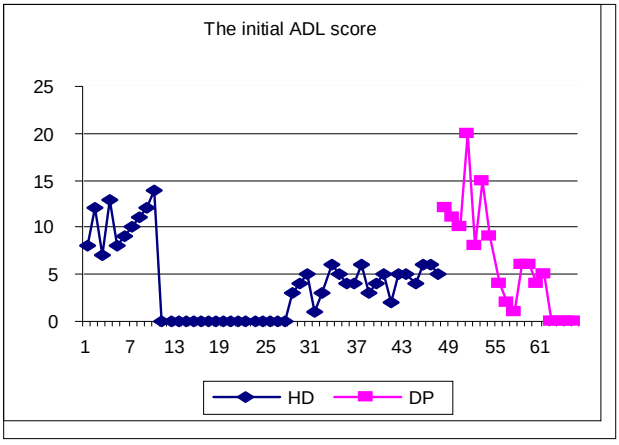

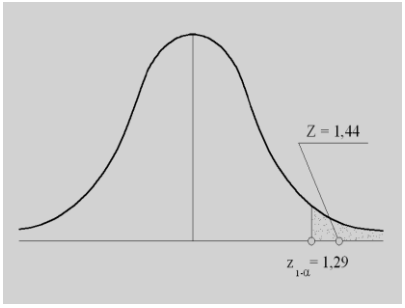

Fig. 5. The median MDS-ADL score was statistically significant higher in CAPD group than in HD group, when dialysis was started

Statistic analysis of the evolution of MDS-ADL score during the study revealed that, in both groups, the MDS-ADL score increased in the third year of the

study. This increment was statistically slower in PD group than in HD group (*Mann-Whitney rank test*) (fig. 6). The success of this attitude (to include in peritoneal dialysis elderly patients with severe initial functional dysfunction) requires patient's family support. In our CAPD elderly group, 12 patients (66.66%) had full assistance from a family member and 6 patients (33.33%) had partial help (one member visiting the patients at least once daily).

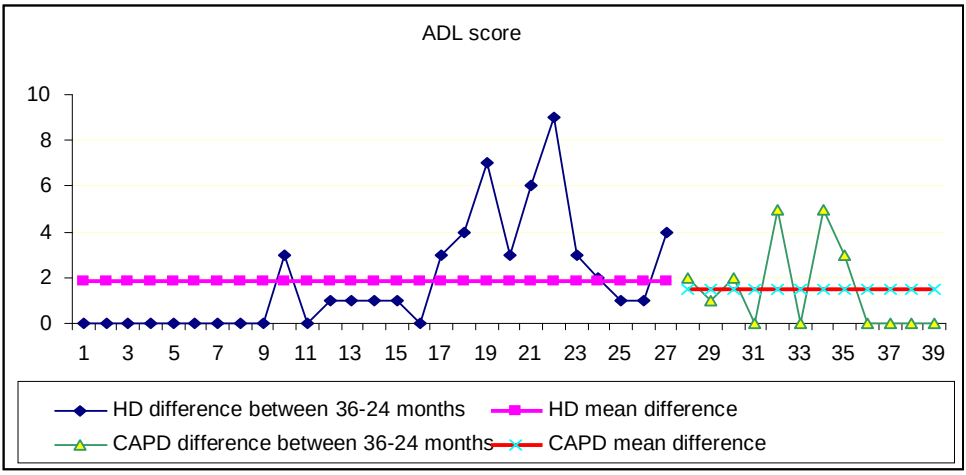

Fig.6. In the third year of the study the MDS-ADL score increased more rapidly in the HD group

CONCLUSIONS

This study – part of a larger research on comparison of peritoneal dialysis versus hemodialysis in elderly – is observing the evolution of functional status for 3 years after starting dialysis. The results conclude that elderly treated with peritoneal dialysis have a better evolution of functional status than hemodialyzed elderly patients do. Protecting vascular stability, lower incidence of severe and/or acute complications, dialysis access and dialysis dose easier to obtain, all of these are possible explanations of the advantages of peritoneal dialysis versus hemodialysis in elderly and of the results obtained in the above study.

NOUTĂȚI

NOILE VALORI ALE PUNCTELOR DE RUPTURĂ STABILITE DE CLSI ŞI SENSIBILITATEA TULPINILOR DE *ENTEROBACTERIACEAE* PRODUCĂTOARE DE BLSE

În 2010, Clinical and Laboratory Standards Institute (CLSI) a redus valorile punctelor de ruptură funcție de care se stabileşte sensibilitatea la unele cefalosporine şi aztreonam pentru speciile de *Enterobacteriaceae* şi a eliminat necesitatea de a efectua screening-ul pentru tulpinile care produc beta-lactamaze cu spectru extins (BLSE) şi testele de confirmare.Wang et al. au efectuat un studiu prin care au incercat să evalueze cât de multe dintre tulpinile producătoare de BLSE ale trei cele mai comune specii de *Enterobacteriaceae* (*Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis*) sunt declarate sensibile la antibiotice beta-lactamice conform noilor valori ale punctelor de ruptură. Sensibilitatea la antibiotice au testat-o prin metoda diluțiilor în mediu solid şi interpretarea au realizat-o funcție de noile valori ale punctelor de ruptură, iar genele care determină producerea de BLSE au fost amplificate prin PCR şi detectate prin secvențiere. Rezultatele au arătat că toate tulpinile de *Enterobacteriaceae* producătoare de BLSE au fost rezistente la cefazolin, cefotaxim, ceftriaxonă, dar un număr substanțial de tulpini producătoare de ESBL aparținând speciilor de *Escherichia coli* şi *Proteus mirabilis* ar putea fi raportate ca fiind sensibile la ceftazidim, cefepim şi aztreonam în conformitate cu noile valori CLSI. Wang et al au explicat rezultatele prin prezența unei prevalențe înalte a tipului CTX-M a BLSE. (Wang P, Hu F, Xiong Z. Susceptibility of extended-spectrum-beta-lactamase-producing *Enterobacteriaceae* according to the new CLSI breakpoints. *J Clin Microbiol* 2011; 49(9): 3127-31).

COMPARATIVE EVOLUTION OF HEMODIALYSIS VERSUS PERITONEAL DIALYSIS IN ELDERLY (Abstract): The prevalence of treated patients with end-stage renal disease (ESRD) has considerably increased in the last decade mainly in the elderly age groups. The type of optimal mode of dialysis therapy in elderly is difficult to establish and most studies comparing hemodialysis and peritoneal dialysis in elderly failed to demonstrate the superiority of one therapy versus the other. The present article uses Charlson Co morbidity Index to compare evolution of an elderly population in HD versus PD. **Material and methods**: Nondiabetic patients (> 65 years) who initiated dialysis therapy for ESRD during January 2006-December 2007. **Results**: In HD group, the median CCI calculated 6 month before initiating dialysis therapy was 5.87, with limits between 3 and 11. At the time of initiating dialysis, the median CCI was 6.55 (limits 3-11). In peritoneal dialysis group, CCI evaluated 6 months before initiating dialysis had a median value of 7.38, with limits between 3 and 11. At the time of initiating dialysis procedure, the median CCI was 7.72. **Conclusions**: This study demonstrates that PD is, in the majority of situations, a better option for dialysis in elderly. **Key words**: END-STAGE RENAL DISEASE, ELDERLY, HEMODIALYSIS, PERITONEAL DIALYSIS, CHARLSON COMORBIDITY INDEX.

Incidence of chronic kidney disease has considerably increased in elderly (> 65 years) as a result of population ageing, the age-related increase in the incidence of hypertension and diabetes mellitus (the main causes of CKD) and the worldwide increase of accessibility to renal replacement therapies.

Data from USRDS (United States Renal Data System) show that in 2008, in the USA – the country with the highest incidence of CKD – the median age of dialyzed patients was 64,4 years (1). Comparative to 1998 (when elderly represented 47% from all dialyzed patients (2)), the raise of ESRD incidence in persons >65 years was of 11%, comparative with 2,4% in 20-44 years age-group and 6,1% in 45-

64 years age-group. In Great Britain, more than 50% of the patients entering dialysis therapy are aged more than 65 years (3). In other words, ESRD have actually become a predominantly geriatric disease; therefore, nephrologists should accumulate increasing knowledge in this field and collaborate with gerontologists as well (4).

The type of optimal mode of dialysis therapy in elderly is difficult to establish and most studies comparing hemodialysis and peritoneal dialysis in elderly failed to demonstrate the superiority of one therapy versus the other (5).

Incidence of co morbidities in elderly with ESRD is extremely high and clinical outcome, as well as the survival, are worse then in younger adults (6). In order to determine the best choice for renal replacement therapy for elderly people, it is necessary to consider the advantages and the disadvantages of each method in this population (7) (table I).

The present article compares the evolution of HD versus DP in an elderly dialyzed population using Charlson co morbidity index (8).

TABLE I

Advantages and disadvantages of peritoneal dialysis and hemodialysis in ESRD patients>65 years

	Peritoneal dialysis	**Hemodialysis**
Advantages	No need of vascular access Longer preservation of residual renal function Patient independence of hospital Can be performed by a family member	Suitable for the majority Independent of patient's ability
Disadvantages	Difficult in anurics or patients with history of abdominal surgical interventions Difficulty in learning the procedure	Risk of intradialytic hypotension Frequent vascular access problems, frequent changes for central catheters, augmented risk for infection

MATERIAL AND METHODS

Nondiabetic patients who initiated dialysis therapy for ESRD during January 2006-December 2007 and who were > 65 years old at the time of initiation were included in the study. The follow-up period was for 3 years from the moment of initiation of therapy, the study ended in December 2010. The patients were classified as HD or PD treated patients only after 3 month of stable dialysis therapy.

In all patients, at the beginning of the study it was recorded the following data: age 65-75 years or > 76 years; gender; GFR at the time of initiation of dialysis calculated with MDRD formula; primary cause of renal failure. Patients' comorbidities were classified using Charlson Co morbidity Index (CCI) (8) calculated at the time of initiation of dialysis and, then, at 6 month interval (table II). Comparisons between HD and DP elderly patients were made. Statistic validation of data was performed using *t* and *z* tests.

AIDS	**4**

* For each decade>40 years, a score of 1 is added.

RESULTS

65 years old elderly ESRD patients have begun dialysis therapy between January 2006-December 2007: 18 on CAPD and 47 on HD.

From all new patients who started CAPD in the mentioned period, elderly represented 47.36%. There were 9 men and 9 women. The patients ≤ 75 years predominated (55.56 % ≤ 75 years, 44.44 % ≥ 76 years); the median age was 73,16 years (limits between 65-82 years). Ischemic nephropathy was the main primary renal diseases (66.7%); in 6 patients it was associated with other cause of renal failure. GFR at the time of initiating dialysis therapy had a median value of 6.68 ml/min, with limits between 4.4 and 8 ml/min.

Elderly who begun HD represented 19.18% from all new hemodialysed patients. The median age was 70.53 years, with limits between 66 and 78 years; 44 patients had ≤ 75 years and 3 ≥ 76 years. There were 29 man and 18 women. The main causes of renal failure were ischemic nephropathy (29.78%) and tubulointerstitial chronic nephropathy (29.78%); etiology of ESRD was mixed in 6 patients. GFR at the time of initiating dialysis therapy had a median value of 6.60 ml/min, with limits between 4.1 and 9,3ml/min.

In peritoneal dialysis group, CCI evaluated 6 month before initiating dialysis had a median value of 7,38, with limits between 3 and 11. At the time of initiating dialysis procedure, the median CCI was 7.72 (limits 4-11).

In HD group, the median CCI calculated 6 month before initiating dialysis therapy

was 5,87, with limits between 3 and 11. At the time of initiating dialysis, the median CCI was 6.55 (limits 3-11).

DISCUSSION

The proportion of elderly treated with CAPD was greater than those treated with HD: 47% in CAPD versus 19% in HD (fig.1). In the CAPD elderly group, there were treated significantly more patients >76 years than in HD elderly group: 44.44% versus 6% (fig.2) – *t* test.

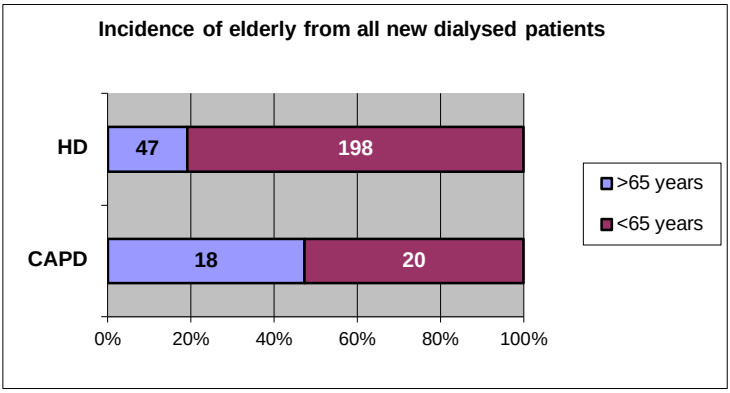

Fig. 1. Incidence of elderly from all dialyzed patients in CAPD versus HD

	CAPD	HD
Median age (years)	73.17	70.53
SD	5.43	3.46
Number of patients (n)	18	47

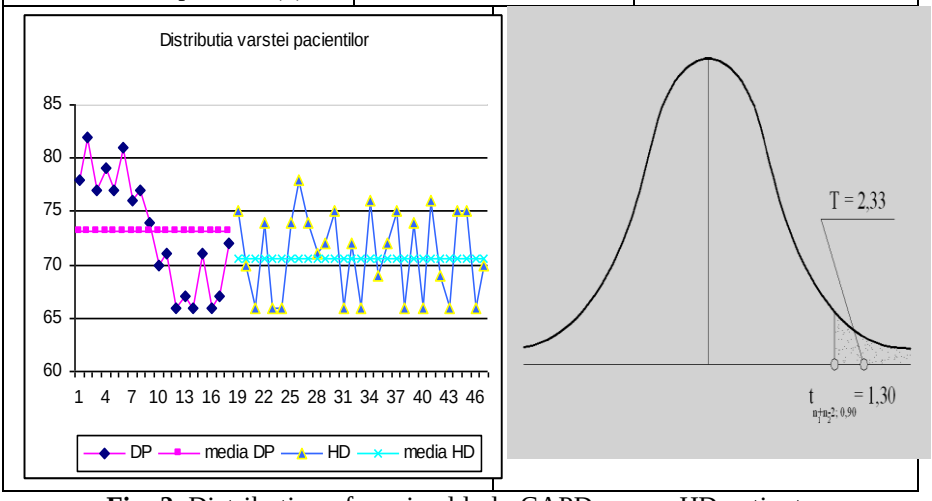

Fig. 2. Distribution of age in elderly CAPD versus HD patients

These data might be explained by the modality of selection of dialysis therapy in elderly in clinical practice. PD is preferred in those situations in which HD would be

associated with multiple risks for patients, meaning: elderly with multiple co morbidities, those with difficulty of transportation to the hospital, those cu hemodynamic instability or those with impossibility to obtain a permanent vascular access.

This observation is supported by the fact that residual GFR at the time of beginning dialysis therapy was comparable between the two studied group (6,68ml/min in PD group and 660. ml/min in HD group), which demonstrates that, in the present study, the selection of elderly for PD was not planned (as theoretically would be expected). Except few cases with severe complications of uremia (pulmonary edema, hyperkalemia – 4 patients in our study) who first needed several HD sessions, in the vast majority of elderly, PD was preferred as first choice of therapy due to severe co morbidities (malnutrition, dementia or other sequel of CVA, angina, hemodynamic instability) with high risk of aggravating in HD therapy.

The fact that, in clinical practice, DP is considered in elderly like an "escape valve" for severe cases is further supported by other two results in our study:

1. CCI at the time of initiating dialysis was more severe in elderly treated with PD (median 7.72) versus those treated by HD (median value 6.55) – *T* test (fig.3). In PD elderly patients there was a predominance of complications of systemic atherosclerosis – especially cerebrovascular and coronary diseases, while in HD elderly patients there was a predominance of congestive heart failure.

2. The primary renal disease (PRD) (fig.4):

- ischemic nephropathies was the PRD in 66% of elderly PD patients versus 30% in elderly HD group (*Z* test);
- several kidney diseases with oligoanuria and the necessity of high ultrafiltration (oliguric glomerulopathies, nephropathies associated with congestive heart failure) or obstructive nephropathies with chronic kidney infections and the necessity of periodic urologic interventions were predominant in HD elderly group

	Charlson index at the time of initiating dialysis therapy		
	Media	**SD**	**N**
CAPD	7.72	1.90	18
HD	6.55	2.19	47

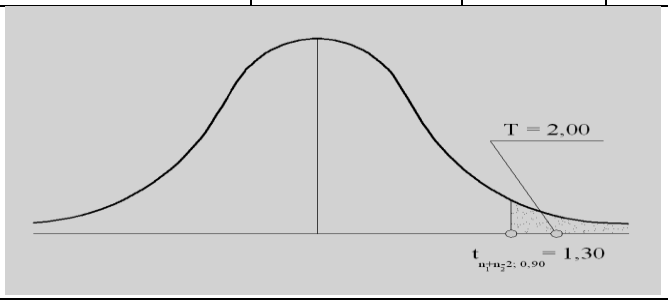

Fig. 3. Charlson Co morbidity Index at the time of initiating dialysis is more severe in CAPD elderly patients

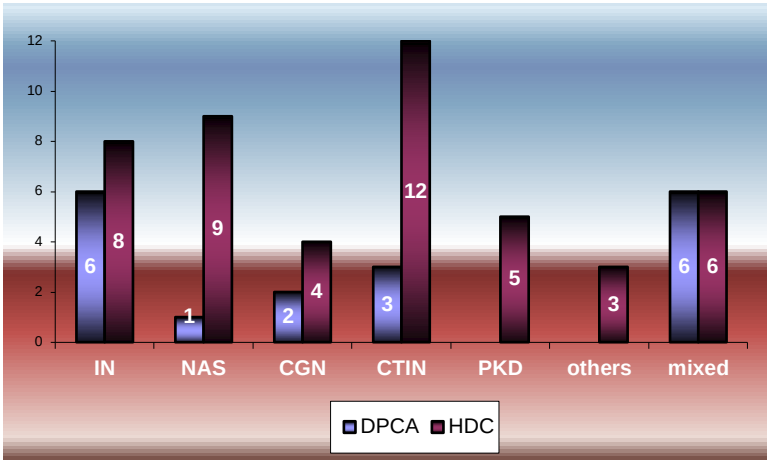

Fig. 4. Comparative distribution of primary renal diseases in CAPD versus HD elderly group

The most important finding in the present study is the comparative evolution of CCI during the 3 years of observation (fig.5). In elderly PD group, it was noted a stability of CCI value for a period of approximately 1,5 years, followed by an increase as a result of several co morbidities aroused in the patients' evolution:

- Cerebrovascular accidents (CVA) were recorded in 3 patients; 1 patient died as a result of the CVA, 2 survived with significant residual dementia and needed help from a family member to perform dialysis sessions and for every day self-care.
- Diabetes complicated the evolution of six DP elderly patients, but there was no need for insulin treatment.
- Heart failure has been registered in four patients, all with ischemic coronary disease and chronic atrial fibrillation. In the presence of a adequate Kt/V in all patients, heart failure was managed with diet and augmented ultrafiltration using high- glucose dialysate or extrarenal. After 6 month one patients had to be transferred on HD because of nonresponsive congestive heart failure.
- Other co morbidities – chronic viral hepatitis (1 patient), pulmonary chronic infections (COPD 2 patients), peptic ulcer (1 patient).

In HD elderly group, CCI increased from the moment of initiating HD; after 6 month, CCI stabilized for a period of 1-1,5 years; after this period, CCI continued to raise with a more rapid rhythm than in DP patients. The main co morbidities in elderly HD were:

- Congestive heart failure complicated the evolution of 27 patients; four died in the 3 years of study.
- CVA was recorded in 14 patients, 3 died.
- Acute myocardial infarction – 7 patients.
- Peptic ulcer disease or hemorrhagic gastritis – 12 patients.
- Chronic pulmonary disease, frequently because of chronic pulmonary status and pulmonary infection – 8 patients.
- Hepatic failure (viral or cardiac) – six

patients.

- Neoplasia – bladder 2 patients, pulmonary one patient, prostate three patients.
- Chronic lymphatic leukemia – 1 patient.

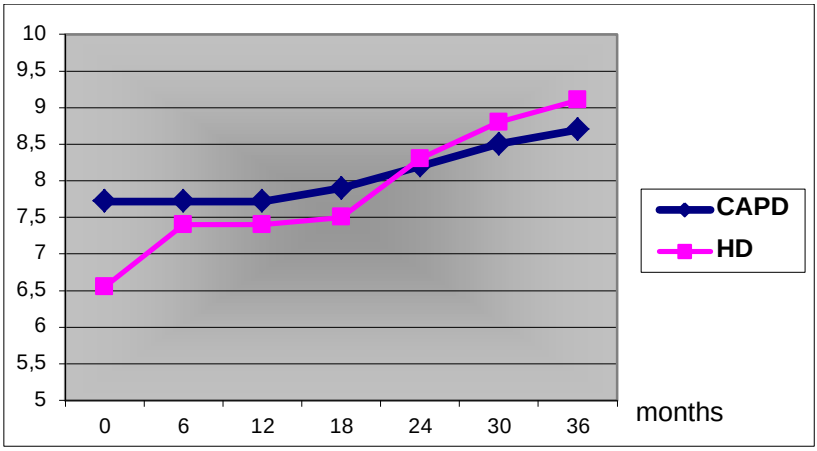

Fig. 5. Comparative evolution of CCI in HD versus PD elderly group

Comparative statistic analysis of the CCI evolution between the two groups revealed significant differences (*t* test): HD elderly patients experienced a greater increase of CCI in the first 6 month and in the second year of therapy, when compared with CAPD elderly patients (table III, table IV). These observations could have several explanations:

- Initiating HD, known to be a more aggressive therapy, may be accompanied, in elderly with hemodynamic instability, by several acute complications: digestive hemorrhage (regular heparin use in elderly with malnutrition and/or heart failure), intradialytic hypotension, angina or cerebral ischemia; CAPD is better tolerated from this point of view.
- Increase of co morbidities incidence in the third year of study in HD patients may be explained by progressive decrease of diuresis with several consequences: congestive heart failure, aggravation of hypertension, arrhythmia. Hepatic failure because of congestive heart failure of chronic viral hepatitis, hemorrhagic cerebral attacks because of uncontrolled hypertension and heparin use may occur in HD elderly quite often.

TABLE III

In the first 6 month after initiating dialysis, there was a significant more increase of CCI in HD elderly group (*T* test)

	CCI at the time of initiating dialysis			CCI at 6 month therapy			**Increase rate**		
	Median	SD	N	Median	SD	N	**Median**	**SD**	**N**
CAPD	7.72	1.90	18	7.72	1.90	18	**0**	**0**	**18**
HD	6.55	2.19	47	7.40	1.84	47	**0.85**	**0.59**	**47**

TABLE IV

Between 18-36 month of follow-up, CCI increased more in HD elderly group than in CAPD treated group (*t* test)

CONCLUSIONS

This study demonstrates that PD is, in the majority of situations, a better option for dialysis in elderly. Of course, severe atherosclerosis – because of ageing, uremia and associated co morbidities – might be a problem for peritoneal capacity of ultrafiltration and/or toxins epuration. Even in this condition, peritoneal dialysis, providing a better hemodynamic stability, may be the optimal treatment for elderly uremics for a limited period (6 months, 1 year) in which it is obtained an improvement of general and nutritional status. Therefore, consulting a nephrologist from early stages of CKD in elderly would allow a better selection of dialysis mode, prevention of co morbidities and finally ameliorate the vital prognosis.

EDITORIAL

CRYOPRESERVATION OF HUMAN EMBRYOS

The first pregnancy resulting from transfer of a thawed cryopreserved human embryo was reported in 1983 in Australia (1), and the first live birth following embryo cryopreservation was reported in 1984 in The Netherlands (2). After the first successful *in vitro* fertilization (IVF) treatment in 1978, the need for an effective cryopreservation program arose from rapid development and improvements of assisted reproductive technology (ART) protocols. Initially, all available embryos were transferred in IVF treatments owing to its low success rate, but improvements of clinical and laboratory aspects of IVF led not only to increased pregnancy rates but also to increased risk of multiple pregnancies. To prevent multiple pregnancies, fewer embryos were transferred and the supernumerary embryos cryopreserved for potential future use (3, 4).

Over the last decade the proportion of ETs derived from freeze-thaw cycles have increased substantially. According to the report by the US Centers for Disease Control and Preventions summarizing the number of assisted reproductive treatments in 2014, one in two of all embryos transferred in the United States had been cryopreserved. The European Society of Human Reproduction and Embryology has reported comparable trends (5). This rise in the number of frozen embryo transfers (FETs) performed can be ascribed to four major developments.

First, the introduction of ovarian hyperstimulation at the start of the 1980s resulted in an increased number of embryos available after each treatment cycle. During the same period rapid developments in laboratory techniques increased both the proportion of oocytes that generated viable embryos as well as the live birth rate (LBR) per embryo transferred. This reduced the need for multiple embryo transfer and increased the storage of supernumerary embryos for later use.

The second key development has been the widespread introduction of elective single embryo transfer (eSET). Extended embryo culture was introduced on the premise that only embryos of excellent quality with the highest potential for implantation will reach blastocyst stage selection (6). By prolonging the in vitro culture up to 5 days and allowing blastocyst stage embryos to develop, time and natural selection would aid clinical embryo selection. The LBR per blastocyst transfer has been demonstrated to be significantly higher compared with cleavage stage ET.

The third major contributor to the number of FET cycles performed has been the widespread replacement of slow freeze cryopreservation by vitrification (7). The slow freeze cryopreservation technique resulted in survival rates varying between 35% and 70%, compared with more than 90% after vitrification.

The latest element to extend the use of FET has been the introduction of "freeze-all" strategies that segment ovarian stimulation in a different cycle from that in which the embryo is transferred (8). This approach is argued to prevent many of the detrimental aspects of ovarian stimulation

on the health of the woman and endometrial function. Evidence from human and animal studies suggests that superovulation leads to histologic changes in the endometrium at the time of implantation. In animal models, superovulation has been shown to affect the depth of the surface epithelium, the number and length of microvilli, and the mitotic activity in the surface epithelium and stromal cells. Both human and animal studies have found that superovulation lowers the expression of specific integrins associated with the window of implantation (9). Freeze-all protocols may improve outcomes in women at risk of ovarian hyperstimulation syndrome and patients who develop an elevated P level at the time of hCG triggering (10). The possible detrimental effect of ovarian hyperstimulation on endometrial receptivity has been suggested to be intermediated by elevated progesterone. Indeed, progesterone elevation (PE) on the day of hCG administration in fresh embryo transfer cycles, a proxy of endometrial receptivity, has been associated with a decreased probability of pregnancy. More precisely, women with a PE of 0.8-1.1 ng/mL had a lower chance of pregnancy compared with women with progesterone levels <0.8 ng/mL (odds ratio [OR] 0.79, 95% confidence interval [CI] 0.67-0.95). In contrast, no effect of PE on pregnancy chances was observed when embryos that resulted from women exhibiting PE on the day of hCG were cryopreserved and transferred in a subsequent cycle (OR 1.03, 95% CI 0.79-1.34). The same results hold for embryo transfers in donor-recipient cycles (OR 1.18, 95% CI 0.76-1.84) (11). The results of several ongoing randomized controlled trials will clarify the place of freeze-all protocols in contemporary practice. However, if these studies show improved outcomes from freeze-all strategies compared with fresh transfer, a further rise in the number of FET cycles is to be expected.

Any women in reproductive age with a sufficiently high risk of developing future ovarian failure (gonadotoxic chemotherapy, radiotherapy, and/or ovarian surgery) may benefit from embryo cryopreservation though the tools of assessment of such a risk are still not very precise. Furthermore, the risk assessment can be influenced by many other factors such as the delay expected after chemotherapy and the number of children desired in the future. Embryo cryopreservation may be indicated in women with curable cancer where conception must be postponed until the resolution of the primary disease and in women with nononcological conditions where reproductive function is threatened. Breast cancer is the most frequent cancer diagnosed in women of reproductive age. Embryo cryopreservation is an attractive strategy for fertility preservation in breast cancer patients who have a partner or who are willing to use donor semen. The process of embryo cryopreservation requires ovarian stimulation, oocyte retrieval, and IVF, which typically requires a delay of 2 to 6 weeks. Because women with breast cancer generally have a window of approximately 6 to 8 weeks between surgery and the initiation of adjuvant chemotherapy, it is feasible to undergo controlled ovarian hyperstimulation.

Because hematological cancers, particularly Hodgkin lymphoma and acute lymphoblastic leukemia tend to occur in a younger population, a large proportion of patients will be candidates for fertility preservation. Each hematological malignancy has a unique constellation of fertility

considerations that relates to the disease itself, the gonadotoxic potential of common treatment protocols, and the age of the patient population.

Pelvic/abdominal radiotherapy is a well-established cause of premature ovarian failure and infertility. Radiotherapy to the ovaries causes DNA damage of somatic and germ cells that is not amenable to repair. Furthermore, the estimated lethal dose to destroy 50% of non-growing follicles present in the ovary is < 2 Grays. Gonadal damage occurs not only by direct exposure of the ovaries following total body, abdominal or pelvic irradiation, but also due to scattering radiation. Age, dose, extent, and type of radiotherapy are important prognostic indicators for development of ovarian failure. Single dose radiotherapy also seems to be more toxic than fractionated doses. These patients can benefit from fertility preservation procedures before treatment including embryo cryopreservation, or alternatively oophoropexy may be considered, especially if an abdominal surgery is already necessary for the treatment of the primary disease.

Surgery on the ovary due to endometriosis or any other benign ovarian condition may diminish ovarian reserve and lead to premature ovarian failure. Ovarian reserve can be further compromised, either due to extensive or progressive disease, or because of bilateral occurrence and repeated surgery. Therefore, fertility preservation procedures, such as embryo cryopreservation, should be considered before surgery in reproductive-age women at risk of ovarian failure.

Women with BRCA 1 and BRCA 2 mutations have a markedly higher cumulative lifetime risk of developing breast and ovarian cancer. While women with BRCA 1 mutation have an estimated 40% to 90% lifetime risk of breast cancer and a 10% to 40% lifetime risk of ovarian cancer, women with BRCA 2 mutations have an estimated 40% to 50% lifetime risk of breast cancer and a 10% to 20% lifetime risk of ovarian cancer. Therefore, prophylactic oophorectomy is suggested as soon as childbearing is completed, or by the age 35 to 40 years depending on the family history, to decrease the risk of ovarian and breast cancer. Embryo cryopreservation can be offered for women in reproductive age with available partner or for women willing to use donor semen who wish to delay childbearing beyond the age of 35 to 40 years. Moreover, women with BRCA mutation may have lower ovarian reserve, requiring multiple cycles to increase the embryo yield and improve subsequent pregnancy chances.

Fertility preservation with embryo cryopreservation is a safe and effective option in women at risk of premature ovarian failure due to medical treatment and interventions. As predicting the likelihood of infertility following gonadotoxic treatments is extremely difficult and this likelihood can be affected by unforeseen factors, fertility counseling should be offered to all females with reproductive potential. In most cases, ovarian stimulation protocols using GnRH antagonists and GnRH agonists for trigger should be preferred in fertility preservation cycles because of time limitations and to reduce the risk of ovarian hyperstimulation syndrome. Patients with estrogen positive receptor cancers can benefit from specific protocols of ovarian stimulation with aromatase inhibitors.

Frozen embryo transfer has been associated with an increased risk of neonates being born large for gestational age (12). This in turn may be associated with a high-

er incidence of perinatal complications, such as shoulder dystocia and the accompanying neonatal and maternal comorbidity. The cause of the reported increase in incidence of large for gestational age offspring after FET remains unclear. Indeed, follow-up studies have indicated a tendency for in vitro-generated embryos to produce slightly smaller babies compared with those spontaneously conceived. It has been proposed that the transfer of embryos into a uterus that has not been subject to the hormonal impact of ovarian stimulation may serve to "unmask" the previously reported tendency of in vitro-generated embryos to produce "large offspring syndrome". Moreover, there is some suggestion that the endometrial preparation method used in FET cycles can influence birth weight, with one study reporting a tendency to a higher birth weight after modified natural cycle FET (mNC-FET) compared with artificial cycle FET (AC-FET) (13). Placenta accreta is another possible obstetric complication that has been reported to arise more frequently after FET (14).

The question regarding the benefit of cryopreservation of all embryos with subsequent replacement in more physiologic cycles is not without controversy. As is the case when new hypotheses are generated, it is hard to filter through the early studies to determine whether there is a publication bias, bias and confounding due to patient selection, or unconscious (or conscious) reporting of only favorable results.

NEWS

CONGENITAL THROMBOPHILIA AND PREGNANCY

A study of a group of researchers from Poland aims to evaluate the relationship between most common polymorphism genes involved in congenital thrombophilia and the incidence of IVH among newborns. This is a single center, prospective,study and includes 100 cases of preterm infants born from 24 to 32 weeks of gestation, exposed to antenatal steroid therapy and without congenital abnormalties, in Hospital of Gynecology and Obstetrics at the University of Medical Sciences in Poznan, Poland, between June 1,2014 and August 15,2016. IVH was diagnosed by routine cranial ultrasound and confirmed by two independent neonatologists.In conclusion, analysis showed a prevalence 4,5 times higher of IVH stages ll to lV in infants born with genotype CC of MTHFR 1298A>C gene polymorphism. In conclusion, this study confirmed that the MTHFR 1298A>C polymorphism is associated with the risk of IVH and did not confirm any significant prevalence of IVH development in other studied mutations polymorphisms. CUTANEOUS THERMOGRAPHIC CHANGES IN DIABETIC POLINEUROPATHY (Abstract): **Aim**: to demonstrate the effectiveness of the thermography method in assessing and diagnosing peripheral polyneuropathy and risk of developing ulcerative lesions in diabetic patients planting. **Material and methods**: Study was prospective and included 90 patients of both sexes, aged between 18 and 70 years in the Neurology Clinic of the Rehabilitation Hospital Iaşi from January 2010-January 2011. The study group consists of 60 patients diagnosed with type 2 diabetes complicated with sensory- motor polyneuropathy. Control group consisted of 30 patients, selected from apparently healthy general population to assess the normal thermographic profile. To register thermic values it was used a thermal infrared camera FLIR A320 type of setting individual emission on the skin areas examined with automatic temperature correction reflected the distance or relative humidity. **Results**: Gender distribution of patients in the study group was predominantly male (63%), the ratio M / F = 1.7 / 1. Motor conduction velocity in the study group was significantly reduced both the SPE (41 ± 2.8 m/s) and SPI (40.5 ± 3.1m/s). Skin temperature was significantly higher in the control group compared with controls, both legs and the plantar surface (33.70 ± 0.80; 28 ± 0.50 t^0C). **Conclusions**: Thermographic changes in patients with sensory-motor neuropathy is an early sign in the detection and prevention of risk of injury planting.Thermography can be a useful method for diagnosis and dynamic evaluation of patients with peripheral sensory-motor polyneuropathy. **Key words**: TERMOGRAPHY CHANGES, DIABETIC NEUROPATHY, MOTOR CONDUCTION VELOCITY.

Termografia are multe aplicaţii în viaţa cotidiană, inclusiv în medicină. Primele încercări au fost făcute în anii 1960, folosind dispozitive mari şi zgomotoase (1). Acestea au fost utilizate în unele studii neinvazive ce implicau evaluarea temperaturii pielii (2). Unul din factorii cheie în termoreglarea organismului uman este pielea, care reprezintă interfaţa dinamică între corp şi mediul său. Imagistica în infraroşu furnizează informaţii cu privire la distribuţia temperaturii pielii. Având în vedere că mediul influenţează temperatura corpului, este important ca pentru orice examinare, metoda trebuie să fie cât mai neutră cu putinţă, şi standardizată (3). Un mare avantaj al termografiei este faptul că nu există contact al dispozitivului cu pielea, în procesul de formare a imaginii nu este utilizată nici o energie dăunătoare, termografia fiind o metodă repetitivă şi neinvazivă. Sistemul nervos periferic şi

central modulează termoreglarea. Implicarea sistemului nervos periferic şi a componentei autonome modifică diferenţiat şi uneori topografic termograma.

Polineuropatie diabetică este o neuropatie senzitivo-motorie, simetrică, care afectează iniţial extremităţile distale ale membrelor inferioare. Studiile arată că aproximativ 18% dintre pacienţi au semne de leziuni ale nervilor în momentul diagnosticului de diabet zaharat, sugerând faptul că scăderea toleranţei la glucoză, este asociată cu neuropatie. Semnele precoce ale neuropatiei diabetice reflectă, probabil, pierderea treptată a integrităţii atât a fibrelor mari mielinizate şi mici mielinice şi amielinice (4, 5).

În contextul acestor caracteristici ale polineuropatiei diabetice periferice, obiectivele acestui studiu au fost de a demonstra eficacitatea metodei termografice în evaluarea şi diagnosticarea polineuropatiei periferice şi a riscului dezvoltării leziunilor ulcerative plantare la pacienţii diabetici.

MATERIAL ŞI METODE

Am efectuat un studiu prospectiv observaţional pe un lot de 90 de pacienţi de ambele sexe, cu vârste cuprinse între 18 şi 70 de ani asistat în Clinica de Neurologie din cadrul Spitalului Clinic de Recuperare Iaşi, în perioada ianuarie 2010-ianuarie 2011. Pacienţii au fost împărţiti în 2 loturi, unul de studiu şi un altul martor.

Lotul de studiu format din 60 de pacienţi diagnosticaţi cu DZ tip 2 (conform criteriilor ADA din 1997 revizuite în 2003 şi 2010) complicat cu polineuropatie senzitivo-motorie (def. conform criteriilor ADA din 1997 revizuite în 2003 şi 2010). Au fost excluşi din acest studiu pacienţii cu polineuropatie de altă etiologie, arteriopatie obliterantă la nivelul membrelor inferioare, ulceraţii plantare, boală cronică de rinichi, insuficienţă cardiacă congestivă,vasculite, boală tiroidiană, afecţiuni cutanate, boală varicoasă şi sindrom edematous al nivelul membrelor inferioare de alte etiologii. Evaluarea lotului a cuprins (i) VCM, (ii) oscilometrie, (iii) termografie. Pentru înregistrarea valorilor termice a fost utilizată o cameră de termoviziune tip FLIR A320 cu setare individuală a emisiei pe ariile cutanate de examinat cu corecţie automată pentru temperatura reflectată, distanţa sau umiditatea relativă. Codul culorilor este albastru, verde, galben, roşu, alb. Prima culoare (albastră) reprezintă zona cea mai rece iar albul cea mai caldă. Culorile au un corespondent numeric echivalent al temperaturii cutanate. Imaginile termografice au fost preluate de la nivelul gambei şi plantei bilateral, făcându-se media temperaturilor obţinute. Pentru realizarea corectă a scanării termografice s-a recurs la următoarele măsuri generale: pacienţii au stat relaxaţi timp de 10 minute pentru acomodarea la temperatura camerei; nu au fost expuse la soare zonele de interes; nu s-a efectuat duş (baie) cu o oră înainte de examinare; nu s-au luat medicamente pentru durere sau vasodilatatorii cu 4 ore înainte de examinare; temperatura mediului ambiental a fost de 25^0 C.

*Lotul martor***,** a fost format din 30 de pacienţi, selecţionaţi din populaţia generală aparent sănătoşi în vederea evaluării profilului normal termografic. Pentru aceasta, am efectuat (i) viteza de conducere motorie, (ii) oscilometria şi (iii) termografia membrelor inferioare.

REZULTATE

Din punct de vedere a caracteristicilor epidemiologice se evidenţiază următoarele aspecte (tab. I):

- vârsta medie semnificativ mai mare la lotul de control comparativ cu lotul martor;

- nu s-au evidențiat diferențe semnificative între sexe;
- mediul de proveniență a fost preponderent urban la ambele loturi de studiu;
- valorile medii ale IMC au fost semnificativ mai crescute la lotul de control.

TABELUL I

Caracteristicile clinice ale loturilor studiate

DISCUȚII

Evaluare termografică a fost realizată la ambele membre inferioare la nivelul gambei şi plantei, s-a obținut o temperatură medie pe pacient iar ulterior o temperatură medie pe un grup de pacienți.

Lotul martor format din 30 de pacienți, cu vârsta medie de 45,2 ± 8,3 ani, a fost examinat conform algoritmului prestabilit. Indicele oscilometric s-a înscris în intervalul de normalitate pentru 100% din cazuri iar VCM a înregistrat valori sub valoarea minimă normal. Evaluarea termografică a evidențiat temperaturi cuprinse între valorile, pentru gambă 30-31,9 şi pentru plantă 25,5-27.

Întrucăt literatura de specialitate nu conferă interval de referință pentru evaluările termografice am considerat aceste valori ca şi valori de normalitate, deoarece pacienții studiați nu au prezentat o altă patologie care să determine tulburări de termoreglare cutanată.

Viteza de conducere motorie la lotul de studiu a fost semnificativ mai redusă atât la nivelul SPE cât şi a SPI. În cadrul loturilor, între sciaticul popliteu intern comparativ cu cel extern nu s-au evidențiat diferențe semnificative ale vitezei de conducere motorie.

Temperatura cutanată a fost semnificativ mai crescută la lotul de studiu comparativ cu lotul martor, atât la gambă, cât şi la plantă.

În cadrul loturilor s-au evidențiat diferențe semnificative ale temperaturii medii ale gambei comparativ cu planta.

Măsurarea temperaturii plantare cu ajutorul radiațiilor infraroşii poate pune în evidență diferențele termice mici dincolo de limita vizibilă, în particular pentru pacienții fără semne inflamatorii sesizabile.

Disfuncția simpatică la nivelul extremităților inferioare duce la scăderea sudorației şi apariția pielii uscate, predispusă la apariția fisurilor şi ulcerațiilor.

Diferențele de temperatură la nivelul tegumentelor membrelor inferioare sugerează că fibrele nervoase mici joacă un rol preliminar în dezvoltarea alterării microcirculației periferice.

CONCLUZII

Temperatura cutanată a fost semnificativ mai crescută la lotul de studiu comparativ cu lotul martor, atât la gambă, cât şi la plantă.

Modificările termografice la pacienții cu neuropatie senzitivo-motorie reprezintă un semn precoce în depistarea şi prevenirea riscului apariției leziunilor plantare.

Termografia poate fi o metodă utilă pentru diagnosticarea şi evaluarea în dinamică a pacienților cu polineuropatie periferică senzitivo-motorie.

Sunt necesare mai multe studii pentru evaluarea specificității şi sensibilității metodei.

BETA-LACTAMASES...UNTIL WHEN? (Abstract): Due to environmental factors and wide use of antimicrobials, only those species that developed their own defense mechanisms shall survive. Enzymatic inactivation is the most common cause of antibiotic resistance. Beta-lactamase production has been described early after the discovery of penicillin and it continues to diversify being now able to inactivate even the most advanced antibiotic. The association with other resistance determinants makes the infection with this kind of bacteria a major therapeutic problem. **Key words**: ANTIBIOTICS, CARBAPENEMS, SUSCEPTIBILITY

Microorganismele au supravieţuit milioane de ani datorită capacităţilor lor de a se adapta la schimbările mediului înconjurător. Astăzi, în era antibioticoterapiei larg răspândite, uneori nejustificată, se exercită o puternică presiune de selecţie asupra populaţiilor microbiene şi doar acele specii ce şi-au dezvoltat mecanisme proprii de apărare pot în continuare supravieţui.

În ultimii 70 de ani, bacteriile patogene şi nepatogene ce alcătuiesc microflora umană au fost expuse unor cantităţii impresionante de substanţe antimicrobiene; se estimează că în SUA se folosesc în jur de 1.600.000 kg de antibiotice anual pentru tratamentul şi profilaxia infecţiilor umane şi de peste 10 ori mai mult în zootehnie şi medicina veterinară.

În ultimul timp auzim vorbindu-se despre aşa-numiţii „super-microbi": stafilococul auriu meticilino-rezistent, microorganismele ESKAPE (acronim de la *Enterococcus faecium*, *S. aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa* şi *Enterobacter spp*.). Mulţi dintre aceştia nu şi-au câştigat acest statut prin creşterea capacităţilor lor de patogenitate sau virulenţă, ci prin gradul înalt de rezistenţă la multiple clase de antibiotice şi prin dificultăţile terapeutice ce au rezultat de aici.

Cel puţin 8 mecanisme principale de rezistenţă a bacteriilor la acţiunea antibioticelor au fost descrise până în prezent: producerea de enzime inactivatoare, scăderea permeabilităţii peretelui bacterian pentru antibiotic, pomparea activă a substanţei antimicrobiene în afara celulei (eflux), modificarea, protecţia sau supra-producerea substratului, *by-pass*-ul lanţului metabolic inhibat sau deturnarea antibioticului de la adevărata ţintă.

Una din cele mai răspândite cauze pentru rezistenţa microorganismelor la antibiotice o reprezintă inactivarea enzimatică a acestora. Distrugerea inelului beta-lactamic de către enzime secretate de bacterii (beta-lactamaze) constituie principalul mecanism de rezis-

tenţă faţă de antibioticele din acest grup.

Beta-lactamazele (BL) au co-evoluat împreună cu bacteriile de mult timp ca factor de protecţie împotriva substanţelor cu acţiune antibiotică din natură, iar în ultimii au cunoscut o răspândire şi diversificare accelerată datorită folosirii pe scară largă a antibioticelor moderne.

Prima BL a fost descoperită în anii 1940, la puţin timp de la descoperirea şi introducerea în folosinţă a penicilinei, la o tulpină de *E. coli* rezistentă. Următorii ani au marcat extinderea rapidă a acestor enzime printre tulpinile de *S. aureus*. Printre bacilii Gram negativi apariţia rezistenţei la ampicilină a fost descrisă începând cu anii 1960 odată cu emergenţa unei BL cu transmitere plasmidică – TEM-1, denumită după numele unui pacient grec la care a fost iniţial descoperită. Acest tip de BL a devenit larg răspândit printre BGN în următorii ani. TEM-10, TEM-12 şi TEM-26 sunt cele mai frecvente pe continentul american.

Ulterior s-a remarcat apariţia unui alt tip de BL denumit SHV, ce sunt înrudite molecular cu cele din familia TEM, fiind transmise prin intermediul plasmidelor.

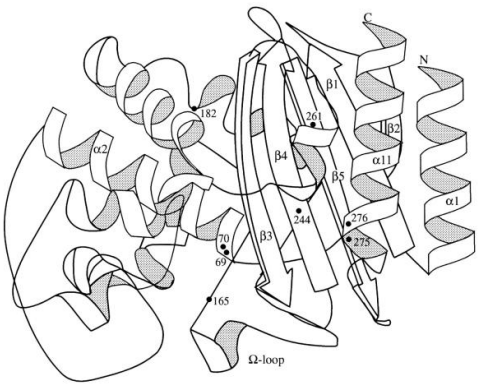

Fig. 1. Reprezentarea schematică sub formă de panglică a BL de clasă A – TEM

Sunt cunoscute mai mult de 50 de subtipuri de SHV, cele mai răspândite în America şi Europa fiind SHV-5 şi SHV-12. Industria farmaceutică a dezvoltat apoi cefalosporinele de generaţia a 3-a ce erau stabile la acţiune acestor beta-lactamaze, doar pentru a asista la apariţia unor alte BL cu spectru extins (ESBL).

La scurt timp după introducerea în folosinţă a carbapenemelor au apărut tulpini bacteriene secretoare de enzime capabile să le inactiveze, iar în prezent răspândirea carbapenemazelor reprezintă o îngrijorare serioasă în lumea medicală datorită tulpinilor de bacili Gram negativi multidrog-rezistenţi pentru care nu avem soluţii terapeutice adecvate.

BL sunt codate la nivel cromosomial sau sunt achiziţionate prin intermediul plasmidelor sau integronilor care pot fi purtătorii mai multor gene de rezistenţă la antibiotice.

În prezent au fost descrise peste 890 sute de BL produse de numeroase specii microbiene şi care pot inactiva selectiv sau în grup penicilinele naturale şi de semisinteză, cefalosporine şi carbapenemi, chiar în asociere cu inhibitori de BL.

Au fost propuse mai multe sisteme de clasificare a BL. Cel descris de Ambler le grupează în 4 clase (A-D) în funcţie de structura enzimatică, pe când cel descris de Bush-Jacoby-Medeiros le structurează în funcţie de tipul de antibiotic inactivat.

Clasele de BL A, C şi D inactivează inelul beta-lactamic al antibioticului folosindu-se de o serină în regiunea lor activă, pe când cele din clasa B sunt metalo-BL ce folosesc zincul pentru a inactiva antibioticul.â

În anul 1983 (Germania) a fost descrisă prima ESBL la o tulpina de *E.coli* dintr-o secţie de terapie intensivă, rezistentă la cefotaximă si ceftazidimă, urmată apoi în 1984 (Franţa) de o tulpina de *Klebsiella pneumoniae*.

TABELUL I
Clasificarea Ambler a beta-lactamezelor

Clasa	Site-ul activ	Tipul de enzimă	Substrat	Exemple
A	Serină	**Penicilinaze**		
		Spectru larg	Benzylpenicilin, aminupeniciline, carboxypenicilins, ureidopeniciline, cefalosporine	PC1 al *Staphylococcus aureus* TEM-1, SHV-1 la *Escherichia coli, Klebsiela pneumoniae*, alte BGN
		Spectru extins (ESBL)	Cefalosporine de generaţia a 3-a şi aztreonam	Enterobacteriaceae: TEM-derived, SHV-derived, CTX-M–derived; PER-1, VEB-1, VEB-2, GES-1, GES-2, IBC-2 la *Pseudomonas aeruginusa*
		Carbapenemaze	Cefalosporine şi carbapeneme	KPC-1, KPC-2, KPC-3 la *K. pneumoniae*; NMC/IMI, SME
B	Metalo-β-lactamaze (Zn^{2+})	**Carbapenemaze**	Cefalosporine şi carbapeneme	IMP, VIM, GIM, SPM, SIM la *P. aeruginusa, Acinetobacter* spp.
C	Serină	**Cephalosporinaze**	Cefalosporine şi carbapeneme	AmpC-type la Enterobacteriaceae, *Acinetobacter baumannii*
D	Serină	**Oxacilinaze**		
		Spectru larg	Aminopeniciline, ureidopeniciline, cloxacilin, methicilin, oxacilin, unele cefalosporine de gen I, II	OXA-family la *P. aeruginusa*
		Spectru extins	Cefalosporine şi monubactami	OXA-derived la *P. aeruginusa*
		Carbapenemaze	Cefalosporine şi carbapeneme	OXA-derived la *Acinetobacter* spp

TABELUL II
Clasificarea Bush-Jacoby-Medeiros a beta-lactamazelor

Grup	Tip	Inhibare de către clavulanat	Clasa moleculară	exemple
1	Cephalosporinaze	Nu	C	*Enterobacter cloacae* P99 (C), MIR-1 (P)
2a	Penicillinaze	Da	A	*Bacillus cereus, Staphylococcus aureus* (B)
2b	Cu spectru larg	Da	A	SHV-1 (B), TEM-1 (P)
2be	Cu spectru extins	Da	A	*Klebsiella oxytoca* K1 (C), TEM-3 (P), SHV-2 (P)
2br	Inhibitor-rezistente	Scăzut	A	TEM-30 (IRT-2) (P)
2c	Carbenicillinaze	Da	A	AER-1 (C), PSE-1 (P), CARB-3 (P)
2d	Cloxacillinaze	Da	D or A	*Streptomyces cacaoi* (C), OXA-1 (P)
2e	Cephalosporinaze	Da	A	*Proteus vulgaris* (C), FEC-1 (P)
2f	Carbapenemaze	Da	A	IMI-1 (C), NMC-A (C), Sme-1 (C)
3	Carbapenemaze	Nu	B	*Stenutrophomonas maltophilia* L1 (C), IMP-1 (P)
4	Penicillinaze	Nu	A	*Burkholderia cepacia* (C), SAR-2 (P)

B- cromosomial şi plasmidic; C - cromosomial ; P – plasmidic

În 1989 în Germania, Argentina, Franţa, Italia – se descrie la Enterobacteriaceae o nouă familie de ESBL - CTX-M ce conferă rezistenţă la cefotaximă si mai puţin la ceftazidimă. Acestea au apărut mai puţin prin mutaţii la nivelul unei gene existente, cât prin achiziţia plasmidică a unui material genetic de la specii de *Kluyvera* (specii de BGN comensali). Aceste ESBL-uri au structura genetică asemănătoare cu TEM sau SHV în proporţie de doar 40%. În prezent sunt cunoscute mai mult de 80 de subtipuri, unele mai active pe ceftazidim decât pe cefotaxim. CTX-M-14, CTX-M-3, CTX-M-2 sunt cele mai răspândite subtipuri, iar CTX-M-15 este cel mai comun subtip asociat *E. coli* din Anglia.

În 1993 (Turcia) se descrie un nou tip de ESBL - PER1 la o tulpină de *Ps. aeruginosa* sensibilă la beta-lactamine doar în asociere cu clavulanat, sulbactam sau tazobactam; în prezent este răspândită şi în Franţa, Italia, fiind frecventă la tulpinile de *Acinetobacter* multirezistente din Coreea.

ESBL de tip VEB1 sau VEB2 sunt descrise (1996) la tulpinile de *E. coli* în Asia de sud-est. Subtipurile GES1 şi GES2, răspândite în Franţa, Grecia şi Africa de sud sunt capabile să hidrolizeze imipenemul.

Subtipul OXA al BL (grup D) hidrolizează oxacilina şi derivaţii săi foarte eficient şi nu este inhibat de către acidul clavulanic. Familia de ESBL-uri OXA-derivaţi sunt produse în special de către tulpini de *Ps. aeruginosa* la care conferă un grad ridicat de rezistenţă faţă de oxymino-β lactami (cefotaxime, ceftazidime, ceftriaxone).

Alte subtipuri de ESBL-uri rare au fost descrise: SFO1 1998 (Japonia) - *Enterobacter cloacae* sensibil la clavulanat si imipenem, BES1 - 1996 (Brazilia): *Serratia marcescens* rezistentă la aztreonam si sensibilă la tazobactam si clavulanat, BEL1 – 2004: *Ps. aeruginosa* sensibilă la clavulanat si imipenem,TLA1 - 1993 (Mexic) la *E.coli*, TLA2 - 2002 (Germania).

BL de tip AmpC sunt codate cromosomial la multe bacterii Gram negative. Mutaţii punctiforme sub presiunea terapiei antibiotice determină o activarea transcripţiei şi rezistenţă la cefalosporinele cu spectru larg. Chiar dacă *E.coli, Salmonella şi Klebsiella* au nativ o exprimare scăzută a enzimelor AmpC, achiziţia plasmidică de materialului genetic le poate conferi rezistenţă la cefamycine şi oxyimino-betalactami, fără sensibilitate la inhibitorii de beta-lactamază.

Carbapenemazele (grup A, B şi D) sunt un grup divers de enzime care în prezent ridică cele mai multe probleme în practica medicală datorită faptului că pot inhiba nu doar carbapenemii ci şi cefalosporinele şi alte peniciline cu spectru larg.

Din grupa A, cel mai frecvent tip îl reprezintă enzimele de tip KPC, iniţial descrise în nord-estul SUA la tulpini de *Kl. pneumoniae*, cu răspândire geografică largă şi prezenţă şi la numeroase tulpini de *E. coli, Citrobacter, Enterobacter, Salmonella, Serratia* sau *Ps. aeruginosa.*

Carbapenemazele de grup B folosesc ionii de Zn^{+} pentru a desface inelul beta-lactamic, sunt susceptibile la chelatori de ioni (gen EDTA) şi nu sunt influenţate de acidul clavulanic, tazobactam sau sulbactam. Aceste enzime conferă rezistenţă la toate antibioticele beta-lactamice (cu excepţia monobactamilor). Sunt regăsite în mod natural la nivel cromosomial la tulpini nepatogene de *Aeromonas, Chryseobacterium* şi *Stenotrophomonas* din mediul înconjurător şi pot fi transmise prin elemente genetice mobile (integroni) la numeroase specii de BGN patogene pentru om. Cele mai importante tipuri sunt incluse în 5 familii: IMP, VIM, SPM, GIM, SIM.

Carbapenemazele de grup D aparţin sub-familiei OXA a BL, cele mai importante (OXA-23, OXA-24, OXA-40, OXA-58) fiind găsite la tulpini de *Acinetobacter baumannii* multirezistent.

În 2008 se izolează la New Dehli (India), de la un pacient suedez de origine indiană cu o infecţie urinară, o tulpină de *K. pneumoniae* rezistentă la toate antibioticele testate, cu excepţia colimicinei. Testele microbiologice şi moleculare efectuate au arătat că aceasta era secretoare de o nouă metalo-beta lactamază (denumită NDM-1) capabilă să hidrolizeze rapid penicilinele, cefalosporinele şi carbapenemele.

Gena ce codifică această nouă ESBL se află localizată la nivelul unei plasmide ce mai conţine o altă BL de tip CMY-4 şi determinanţi de rezistenţă pentru eritromicină, ciprofloxacină, rifampicină, cloramfenicol, cât şi o pompă de eflux şi promoteri ai creşterii microbiene.

Această plasmidă se transmite cu uşurinţă printre membri ai familiei enterobacteriacee, fiind găsită de cercetători indieni din Mumbai la 22 de tulpini carbapenem-rezistente de *Klebsiella* (10), *Escherichia coli (9), Enterobacter (2), Morganella morganii (1).* Studii mai recente au arătat că tulpini secretoare de NDM-1 sunt prezente în numeroase ţări de pe mai multe continente (Bangladesh, India, Pakistan, Anglia, SUA, Israel, Turcia, China, India, Australia, Franţa, Japonia, Kenya, Singapore, Taiwan, ţările nordice). Chiar dacă cazurile iniţiale au fost asociate cu călătorii în India, datorită uşurinţei cu care acest element genetic este transmis inter-specii se aşteaptă apariţia unor cazuri cu transmitere secundară locală.

DATE EPIDEMIOLOGICE

Cu toate că antibioticele beta-lactamice sunt folosite din abundenţă în întreaga lume, distribuţia geografică a BL nu este uniformă. Există spitale (în SUA) în care nu există tulpini bacteriene secretoare de BL, iar în altele până la 40% din cele de *K. pneumoniae* sunt ceftazidim rezistente ca urmare a secreţiei de ESBL.

ESBL-urile sunt cel mai probabil a fi prezente la tulpini de *K. pneumoniae, K. oxytoca* sau *E. coli*, dar au fost raportate şi la citrobacter, enterobacter, proteus, salmonella, serratia, la alte bacterii enterice şi nonenterice ca *Acinetobacter baumannii* sau *P. aeruginosa*. Rata cea mai mare de producere a BL o au tulpinile izolate din secţiile de terapie intensivă.

În Europa numărul tulpinilor de BGN rezistente la antibioticele beta-lactamice este în creştere. Din cele de *E. coli* izolate in hemocultura a fost descrisă rezistenţa la cefalosporine în 28% din ele în Bulgaria, 16% în Cipru şi România şi 12% în Portugalia. Studiul Mystic (Rusia şi Polonia) a arătat o creştere a rezistenţei la cefalosporine între 1997 şi 2004 a *E.coli* de la 2,1% la 10,8 % şi a *Klebsiella pneumoniae* de la 9% la 13,6% .

Studii din Spania au arătat o creştere (între anii 2000 şi 2006) a tulpinilor bacteriene comunitare secretoare de BL de *K. pneumoniae* de la 2.7 la 8% şi de *E. coli* de la 0.5 la 6%. În Italia (în 2003) 7.4% din tulpinile izolate în spital şi 3.5% din cele comunitare erau secretoare de BL.

Factorii de risc pentru colonizarea sau infecţia cu bacterii secretoare de beta-lactamaze sunt diferite de cei pentru achiziţia de infecţii nosocomiale.

Dintre cei mai frecvenţi întâlniţi în mediul spitalicesc (mulţi aflaţi în inter-relaţie) se pot aminti:

- Durată prelungită de spitalizare
- Internare prelungită în secţia de TI
- Gravitate crescută a bolii
- Folosirea de catetere (arteriale sau venoase) centrale
- Utilizarea de catetere urinare
- Ventilaţia asistată
- Hemodializa
- Proceduri chirurgicale abdominale efectuate în urgenţă
- Colonizarea anterioară a tubului digestiv

La pacienţii cu infecţii comunitare factorii de risc pentru prezenţa de tulpini secretoare de ESBL sunt diferiţi şi cuprind:

- terapie cu cefalosporine (II şi III)
- spitalizare in ultimele 3 luni
- terapie cu fluorochinolone
- terapie cu peniciline
- antibioterapie un ultimele 3 luni
- vârsta > 60 ani
- diabet zaharat

DIAGNOSTIC

Detectarea tulpinilor de BGN producătoare de BL se bazează pe laboratorul de microbiologie şi uneori pe constatarea eşecului clinic în terapia acestui tip de infecţii cu cefalosporine cu spectru larg.

Punerea în evidenţă a microorganismelor secretoare de BL poate fi dificilă pentru multe laboratoare datorită faptului că metodele de rutină pentru monitorizarea scăderii susceptibilităţii la oxyimino-cehalosporine şi aztreonam nu sunt suficient de sensibile pentru a detecta tulpinile secretoare de BL, în special de tip TEM-1, TEM-12 or SHV-2.

Există mai multe teste de screening pentru prezenţa beta-lactamazelor. Evidenţierea rezistenţei la ceftazidimă, indiferent de metoda folosită are o bună sensibilitate pentru secreţia de BL. Unii autori susţin folosirea rezistenţei la cefpodoxima ca test pentru producerea de BL.

Performanţele oricărui test ce foloseşte cefalosporine cu spectru larg este influenţată de zona geografică şi particularităţile locale de distribuţie a BL-lor. Într-un studiu al ESBL-urilor de tip SHV-3, toate tulpinile testate in vitro au fost rezistente la ceftriaxonă şi doar 50% la ceftazidim.

Recomandările actuale pentru detecţia producerii de ESBL-uri la tulpinile de *E. coli* sau *K. pneumoniae* sunt de a efectua un test screening iniţial cu 2 din următoarele antibiotice beta-lactamice: cefpodoxime, ceftazidime, aztreonam, cefotaxime sau ceftriaxone. Izolatele cu o CMI > 1 microg/ml trebuie confirmate fenotipic folosind ceftazidime plus ceftazidime/acid clavulanic şi cefotaxime plus cefotaxime/acid clavulanic. Orice tulpină la care se constată o scădere de minim 3 ori a CMI pentru oricare antibiotic folosit în asociere cu acidul clavulanic faţă de antibiotic izolat este considerată ca secretoare de ESBL.

Caracterizarea genotipică a tulpinilor detectate ca secretoare de ESBL este rezervată laboratoarelor specializate şi cercetării ştiinţifice.

MĂSURI TERAPEUTICE

Sensibilitatea in-vitro a microorganismelor producătoare de ESBL-uri variază şi chiar dacă sunt rezistente la unele antibiotice beta-lactamice, pot fi sensibile la altele.

Cele secretoare de BL de tip TEM şi SHV sunt aparent sensibile la cefepime sau piperacillin–tazobactam, cu toate că prezintă un efect de inoculum (scăderea sensibilităţii odată cu creşterea inoculumului de la 105 la 107).

Speciile secretoare doar de ESBL-uri sunt sensibile la carbapeneme şi cefamicine (cefoxitin şi cefotetan) fără a avea efect de inoculum. Cele secretoare de AmpC sunt rezistente la oxyimino-βlactami şi la cefamicine, dar îşi păstrează sensibilitatea la carbapeneme.

Tulpinile secretoare de carbapenemaze de tip IMP, VIM şi OXA rămân sensibile la aztreonam.

Din păcate, multe dintre speciile secretoare de BL au şi alţi determinanţi de rezistenţă pentru antibiotice non-betalactamice (în special pentru amino-glicozide şi fluorochinolone), ceea ce face terapia acestor tipuri de infecţie extrem de dificilă.

Există puţine studii in vivo care să determine tratamentul optim pentru infecţiile produse de tulpini secretoare de ESBL-uri. Pentru infecţiile determinate de *E. coli* sau *Klebsiella spp.* tratamentul cu imipenem sau meropenem s-a asociat cu cea mai bună rată de vindecare clinică şi microbiologică.

Cefepime sau piperacillin–tazobactam au fost mai puţin eficiente.

Tratamentul infecţiilor cauzate de tulpini (în special de *K. pneumoniae*) producătoare de carbapenemaze este o problemă dificilă şi de actualitate. Unele studii afirmă că în ciuda prezenţei acestor enzime, o asociere dintre un carbapenem la doze crescute şi un alt antibiotic activ ar putea avea rezultate pozitive. Alţi autori au folosit cu succes tigeciclina sau aminoglicozidele, pe când monoterapia cu colimicină pare să nu fie atât de eficientă.

În cazul sepsis-ului, VAP sau a rezistenţei la ertapenem se pot folosi imipepemul sau meropepemul.

Ertapenemul este indicat pentru infecţiile urinare complicate, infecţiile intraabdominale sau ale piciorului diabetic.

Fluorochinolone pot fio alternativă în cazul alergiei la carbapeneme; nitrofuratoinul sau fosfomicina pot fi o soluţie în terapia infecţiilor urinare joase şi necomplicate, iar tigeciclina, colistinul sau polimixina B la pacienţii alergici la beta-lactamine.

MĂSURI PREVENTIVE

La nivel individual:

- atenţie la tratament cu cefalosporine (III) aztreonam si cefuroxima
- atenţie la cateterisme
- igiena pacientului

La nivel institutional:

- restricţie pentru cefalosporine
- atenţie la internarea purtatorilor ESBL
- determinări pentru contaminarea cu ESBL

Limitarea transmiterii tulpinilor de BGN secretoare de BL ar putea fi realizată prin implementarea unor măsuri specifice de luptă împotriva infecţiilor nosocomiale. Spălarea frecventă şi corectă pe mâini a personalului de îngrijire, purtarea de mănuşi de unică folosinţă şi a halatului în asociere cu măsuri educative scad riscul răspândirii infecţiilor cu aceşti super-microbi.

Măsuri de control al folosirii cefalosporinelor cu spectru larg şi cunoaşterea spectrului de rezistenţă locală a patogenilor sunt indicate în toate secţiile de terapie intensivă. Interzicerea folosirii de primă intenţie a imipenemului, piperacillin–tazobactamului sau asocierea cefepime–amikacin a condus la scăderea frecvenţei infecţiilor cu tulpini producătoare de ESBL-uri.

Există studii care atestă limitarea acestor tipuri de infecţii prin folosirea de măsuri stricte de izolare pentru pacienţii diagnosticaţi în absenţa controlului antibioticoterapiei.

Folosirea în exces a carbapenemelor (imipenem) pentru tratarea infecţiilor cu BGN rezistenţi la cefalosporine poate duce la apariţia de tulpini secretoare de carbapenemaze (în special *Acinetobacter spp. , K. pneumoniae* secretoare de AmpC (ACT-1)).

În continuare, bacteriile depăşesc cu uşurinţă eforturile lumii medicale actuale de a le stăpâni răspândirea, iar industria farmaceutică este deseori neputincioasă în faţă multitudinii de mecanisme de rezistenţă pe care acestea le dezvoltă rapid şi apoi le transmit rudelor lor mai apropiate sau îndepărtate. Bacteriile ne sunt superioare ca număr, ca rapiditate a înmulţirii şi prin metodele ingenioase şi eficiente prin care pot schimba informaţia genetică necesară supravieţuirii într-un mediu ostil, populat de antibiotice folosite de multe ori excesiv şi fără discernământ de către medicina umană, veterinară sau în agricultură.

NOUTĂȚI

PAUZA MINȚII: PERSPECTIVE TEMPORALE PENTRU ADULȚII CU ADHD

Încadrat în categoria tulburărilor comportamentale, ADHD apare la copil sub forma unor manifestări hiperkinetice cu deficit de atenţie, dar se apreciază că în proporţie de 60% persistă şi la vârsta adultă. Dacă la copil ADHD afectează un număr mult mai mare de băieţi decât de fete, la adulţi procentul devine egal, compromiţând cariera şi relaţiile cu cei din jur. Adultul afectat de ADHD este dezorganizat, copleşit de responsabilităţi, impulsiv, cu tulburări de memorie, nu se poate adapta şi este depăşit de termenele – limită; riscul său de a face depresie este de 5-6 ori mai mare decât al unei persoane normale. Studii recente relevă faptul că depresia şi anxietatea care se instalează atrag după sine diverse dependenţe: 40-44% din adulţii cu ADHD sunt fumători, dependenţi de alcool sau droguri. Perturbarea oricărei activităţi de planificare şi management a timpului rămâne principala dominantă la adult, iar terapia ridică numeroase semne de întrebare. (Carelli M.G., Wiberg B.Time Out of Mind : Temporal Perspective in Adults with ADHD. *J Atten Disord* 2011; 13(1):234-37).

UPPER-EXTREMITY DEEP VEIN THROMBOSIS: CURRENT CONCEPTS IN DIAGNOSIS AND TREATMENT (Abstract): Upper-extremity deep vein thrombosis is a rare manifestation of venous thromboembolic disease. In the past few decades, the clinical importance of upper-extremity deep vein thrombosis has increased because of the wider use of central venous catheters and the development of ultrasonography as a simple and accurate objective diagnostic method. Primary upper-extremity deep vein thrombosis is a rare disorder (2 per 100,000 persons per year), which comprises (1) Paget-Schroetter Syndrome, also known as effort thrombosis, and (2) idiopathic upper-extremity deep vein thrombosis. Secundary upper-extremity deep vein thrombosis develops in patients with upper extremity central venous catheters, pacemakers or cancer and accounts for most cases of upper-extremity deep vein thrombosis. The imaging modes used for diagnosis are: duplex ultrasound, magnetic resonance. Contrast venogram is the standard diagnostic test for characterization of the anatomy. A staged, multimodal approach to Paget-Schroetter Syndrome can effectively restore venous patency, reduce the risk of rethrombosis, and return the patient to normal function. Primary care physicians should be aware of this condition and its atypical presentations, because delayed recognition in a high-functioning persons can be potentially disabling. **Key words**: DEEP VEIN THROMBOSIS, UPPER-EXTREMITY, PAGET-SCHROETTER SYNDROME, SUBCLAVIAN VEIN.

Tromboza venoasă profundă (TVP), denumită şi flebotromboză acută sau uneori tromboflebită profundă, este o afecțiune datorată producerii unui trombus, de obicei puțin aderent, într-o venă profundă. De regulă, este afectată o venă proximală sau distală a extremităților, bazinului, venele cave sau o venă profundă a gâtului, care sunt obstruate complet sau parțial de un trombus; TVP poate fi cantonată şi în sinusurile venoase sau la nivelul diferitelor organe, mai ales abdominale, inclusiv la nivelul venei porte (1).

Tromboza venoasă profundă a extremității superioare (UEDVT; TPMS) se referă la tromboza venelor axilară şi/sau subclaviculară. Din punct de vedere patogenic sunt clasificate ca primare şi secundare. TPMS secundară este mai frecventă (60% din cazuri) comparativ cu cea primară şi întâlnită la pacienți cu catetere venoase centrale, pacemakere sau cancere (2). TPMS primară este o afecțiune rară (2 la 100000 de persoane/an) şi cuprinde sindromul Paget-Schroetter (PSS) cunoscut ca şi tromboză de efort şi forma idiopatică

care poate fi asociată cu un cancer ocult (3). Într-un studiu, 1/4 dintre pacienții care s-au prezentat cu UEDVT idiopatică au fost diagnosticați cu neoplasme (cel mai frecvent cancer pulmonar sau limfom) în primul an de monitorizare. Majoritatea acestor cancere au fost descoperite în timpul primei săptămâni de spitalizare pentru tromboza venoasă (4).

Tromboza spontană a venelor extremității superioare a fost descrisă pentru prima dată de patologul francez Leon Jean Baptiste Cruveilhier (1791-1874) în 1816, în teza sa de doctorat, iar Sir James Paget, 1 st. Baronet, în 1875, o considera posibila cauză a durerii acute şi a tumefierii brațului (5). Primul care a relatat manifestările clinice ale ocluziei trombotice a venelor axilară şi subclaviculară a fost, în 1884, Leopold Schrötter Ritter von Kristelli (6). Termenul de maladie Paget-Schrötter a fost introdus mai târziu, după 1900, de E. S. Hughes (7). În literatură mai este denumită ca şi: Paget-Schrötter syndrome, Schrötter's syndrome, von Schrötter syndrome sau "tromboza indusă de efort".

ETIOPATOGENIE

Triada lui Virchow (1856), adică staza venoasă, leziunea peretelui venos şi hipercoagulabilitatea sângelui constituie cauza trombozei venoase. Cel mai adesea coexistă doi sau toți cei trei factori. În consecință, o varietate de situații clinice sunt asociate cu risc crescut de tromboză venoasă (tab. I) (8).

TABELUL I

Condiții asociate cu un risc crescut pentru dezvoltarea trombozei venoase

Chirurgie Procedee ortopedice, toracice, abdominale şi genitourinare
Neoplasme Pancreas, plămân, ovar, testicule, tract urinar, sân, stomac
Traumatisme Fracturi ale coloanei vertebrale, pelvisului, femurului, tibiei; leziuni ale măduvei spinării
Imobilizarea Infarct miocardic acut, insuficiență cardiacă congestivă, accident vascular cerebral, convalescență postoperatorie
Sarcina
Utilizarea estrogenilor (substituție sau contracepție)
Stări de hipercoagulabilitate Deficiențe de antitrombină III, proteină C sau proteină S; rezistență la proteina C activată; anticorpi antifosfolipidici; boli mieloproliferative; disfibrinogenemia; coagularea intravasculară diseminată
Venulita Trombangeita obliterantă, boala Behçet, homocisteinuria
Tromboză venoasă profundă precedentă

O echipă de medici ai şcolii medicale Harvard, Boston, a realizat un studiu multicentric prospectiv în rândul pacienților cu TVP din Bringham and Woman's Hospital. Au comparat caracteristicile demografice, simptomele, factorii de risc, profilaxia şi

managementul terapeutic şi au evidenţiat factorii predictivi independenţi pentru UEDVT neasociaţi cu CVC: vârsta < 67 ani, BMI < 25 kg/m^2 şi spitalizarea; cateterul venos central a fost cel mai puternic factor independent predictiv pentru UEDVT (odds ratio – OR=7,3; interval de confidenţă – CI = 95%, 5,8-9,2). Concluzia studiului a fost că factorii de risc ai UEDVT diferă de factorii de risc convenţionali ai TVP a membrelor inferioare (9).

Un alt studiu a evaluat influenţa parametrilor genetici şi dobândiţi ai trombofiliei la pacienţii cu UEDVT internaţi in clinica Hematologie a Spitalului Universitar Rotterdam "Dykzigt". Prevalenţa tulburărilor de coagulare nu a fost diferită semnificativ in rândul pacienţilor cu UEDVT spontană comparativ cu cei cu factor predispozant (CVC montat). Pe baza acestor rezultate s-a concluzionat că anticorpii antifosfolipidici sunt frecvent identificaţi la pacientii cu UEDVT (10). Mecanismul trombozelor venoase prin anticorpi antifosfolipidici este necunoscut; se presupune că ei acţionează pe plachete şi endoteliu vascular, producând ocluzie trombotică noninflamatorie a vaselor mari şi mici (11).

Mutaţia genei protrombinei a fost descoperită în 1996 de Poort şi colaboratorii săi. Aceasta se datorează unei substituţii nucleotidice (guanina este inlocuită cu adenina) la nivelul perechii de baze 20210, situată în regiunea 3' netranslatată a genei factorului II. Mutaţia se asociază cu niveluri de protrombină mai mari cu 30% decât normalul, care vor induce o stare de hipercoagulabilitate uşoară, ce poate predispune la tromboză venoasă. După mutaţia factorului V Leiden, mutaţia genei protrombinei G2021A reprezintă a doua cauză de trombofilie ereditară, fiind demonstrată în ~ 20% din cazuri şi este depistată la 6-8% dintre pacienţii aflaţi la primul episod de TV. S-a constatat, de asemenea, că riscul de TVP este de 16,3 ori mai mare la pacientele care folosesc contraceptivele orale şi sunt purtătoare ale mutaţiei, în comparaţie cu lotul martor (12).

Studiile au dovedit că contraceptivele combinate cresc cantitatea de factori ai coagulării VII, VIII (factorul von Willebrand), IX şi X şi cantitatea de fibrinogen. Astfel se explică frecvenţa TVP şi a emboliilor de circa 3 ori mai mare. Tendinţa la tromboză este legată de componenta estrogenică a medicaţiei (16), probabil prin dilataţia venoasă pe care o provoacă, diminuarea eliberării de activatori endoteliali ai plasminogenului şi scăderea concentraţiei de antitrombină III (AT III) (12).

Tumorile osoase benigne primare, incluzând osteocondromul, localizate la nivelul claviculei sunt rare. Departamentul de Ortopedie şi Reabilitare al Universităţii Iowa a raportat un caz atipic în care un osteocondrom s-a dezvoltat în partea medială a claviculei şi a cauzat sindrom de apertură toracică superioară cu tromboză primară a venei subclaviculare (sindrom Paget Schroetter), parestezii în teritoriul plexului brahial şi durere mecanică sternoclaviculară la un tânăr sănătos. Din informaţiile de la acea dată se pare că au fost primii care au raportat un caz de TOS (sindrom de apertură toracică superioară) produs de un osteocondrom al părţii mediale a claviculei. Celelalte două cazuri de tumori mediale de claviculă citate în literatură au fost asimptomatice (13).

DIAGNOSTIC

De obicei există o legătură temporală şi cauzală între activităţile implicând hiperabducţia membrului superior şi geneza

trombozei (14). Pacienții tineri, sănătoşi dezvoltă spontan UEDVT, de obicei în brațul dominant, după activități fizice intense, dar şi ca urmare a unei poziții nefiziologice prelungite a brațului. Efortul intens provoacă microtraume la nivelul intimei vasculare şi conduce la activarea cascadei coagulării. O importantă tromboză se poate produce dacă obstrucția mecanică a peretelui vascular este prezentă (11, 12). Hipertrofia musculară este o cauză neobişnuită de compresiune extrinsecă venoasă. Compresiunea venei subclaviculare apare de obicei la tinerii cu hipertrofie musculară coracobrahială şi a capului scurt al bicepsului care fac abducția completă a brațelor (13). Hiperabducția şi retroversia brațului, în special cu mişcări bruşte, pot luxa artera şi vena axilară şi subclaviculară determinând prinderea acestora între clavicula şi prima coastă. Aceasta determină lezarea intimei venoase şi inițiază tromboza venoasă (14).

Debutul în forma primitivă este imediat sau la interval scurt după un episod de abducție ipsilaterală şi rotație externă repetitive şi susținute, cu rigiditatea brațului şi edemul mâinii. Durerile sunt uşoare sau moderate. Ulterior edemul progresează şi apare circulația subcutanată vicariantă. Venele cutanate ale membrului afectat şi cele din regiunile pectorală şi scapulară se dilată. Vena axilară trombozată poate fi greu de palpat, cordonul venos devenind bine palpabil numai dacă tromboza se extinde şi la vena brahială. Emboliile sunt foarte rare, sindromul posttrombotic este mai frecvent (tendință la recidive), iar evoluția spre *phlegmasia caerulea* lipseşte (15).

Tabelul II descrie testele fizice de provocare utilizate în cursul examenului fizic al pacientului (3).

TABELUL II

Teste fizice de provocare

Test diagnostic	**Manevra**	**Test pozitiv**	**Mecanism**
Adson (scalen)	Pacientul este instruit să inspire profund şi să-şi țină respirația în timp ce gâtul este întins complet şi capul întors către zona afectată.	Pierderea sau scăderea pulsului radial saau reproducerea simptomelor neurologice sugerează un test pozitiv.	Testul Adon (scalen) provoacă îngustarea spațiului dintre mușchii scaleni anterior şi mijlociu, rezultând compresia arterei subclaviculare şi a plexului brahial.
Halsted (costoclavicular)	Pacientul este instruit să-şi aranjeze umerii într-o poziție militară (trași din spate şi în jos).	Pierderea sau scăderea pulsului radial saau reproducerea simptomelor neurologice sugerează un test pozitiv.	Testul Halsted (costoclavicular) este folosit pentru a diminua spațiul costoclavicular dintre prima coastă şi clavicula, determinând astfel compresia neurovasculară.
Wright (hiperabducție)	Pentru a realiza testul, brațul pacientului este în hiperabducție 180º.	Pierderea sau scăderea pulsului radial saau reproducerea simptomelor neurologice sugerează un test pozitiv.	Testul Wright (hiperabducție) determină compresia structurilor neurovasculare în regiunea subcoracoidă de către tendonul mușchiului pectoral, capul humeral sau procesul coracoidian şi mușchii/tendoanele inserate pe acesta.

Alte semne clinice pot fi observate în TVP a membrelor superioare, cum ar fi: subfebrilitate care poate fi atribuită trombozei sau febră mare sugestivă pentru o tromboflebită septică; tahicardia poate fi prezentă dacă există embolie pulmonară sau obstrucția venei cave superioare; sindrom Paget-Schroetter atipic, cu hipertensiunea pulmonară ca rezultat al emboliei pulmonare. Uneori, pacientul poate prezenta o tumefactie localizată a brațului și fetei, sau poate avea asociate simptome vizuale sau vestibulare, în funcție de locul obstrucției (16).

Un istoric de traumatism, sondă á demeure și status trombofilic trebuie excluse pentru a distinge sindromul Paget-Schroetter de forma secundară a trombozei venoase axilară/subclaviculară. Diagnosticul este confirmat de venogramă sau de ultrasonografia dublă. Rareori, tromboza secundară poate debuta în vena cavă superioară și se extinde retrograd. Emboliile sunt rare în absența transformării în phlegmasia caerulea, și ea foarte rară (17).

Eritemul localizat, sensibilitatea dureroasă la palpare și parestezиile sunt simptome nespecifice și pot apărea în celulite, limfedem, compresia neoplazică a vaselor de sânge, leziuni musculare sau tromboză venoasă superficială (tab. III). Mai puțin de jumătate dintre acești pacienți au dovezi imagistice pentru UEDVT. De aceea, este important a confirma sau exclude diagnosticul utilizând teste obiective (18).

TABELUL III

Semne și simptome ale trombozei venei axilare și subclaviculare versus sindromul aperturii toracice.

Afecțiunea	Simptome	Semne
Tromboza axilară subclaviculară	Disconfort vag al umărului și gâtului; edemal brațului și mâinii	Plenitudine supraclaviculară, cord palpabil, edem /cianoză a extremității, distensia venei jugulare, vene dilatate, imposibil accesul cateterului.
Sindromul aperturii toracice	Durere ce iradiază în braț; scăderea forței de prehensiune.	Sensibilitate dureroasă la nivelul plexului brahial, atrofia brațului/mâinii, test Adson sau Wright pozitiv.

Ultrasonografia dublă este primul test imagistic ales în scop diagnostic deoarece este neinvaziv și demonstrează o înaltă sensibilitate și specificitate pentru UEDVT periferică (jugulară, subclavicular distal, axilară). Rezultate fals negative se produc datorită umbrelor acustice ale claviculei care limitează completa vizualizare a venei subclaviculare (19).

Imagistica prin rezonanță magnetică a vaselor și a țesuturior moi este o metodă neinvazivă utilizată pentru a detecta trombii dintr-o regiunea anatomică dificil de abordat. În prezența trombozei, angiografia prin rezonanță magnetică are o bună corelație cu venograma de contrast când a doua este contraindicată (tab. IV) (20).

Venograma de contrast este testul diagnostic standard, ce poate fi efectuat preoperator în intervenții precum infuzia direcționată pe cateter a tromboliticelor, instrumente mecanice precum Angiojet, în angioplastie și urmărirea prin venograme pentru a aprecia răspunsul la intervenție (20).

Flebografia membrului superior este un examen radiologic ce presupune opacifie-

rea axului venos al acestuia prin injectare directă intravenoasă a substanței de contrast. În achiziția fluorografică, avantajul achiziției sub control scopic şi digitalizarea permit vizualizarea întregului ax venos cu o singură injectare (21).

TABELUL IV

Teste imagistice utilizate; riscuri şi beneficii.

Test diagnostic	Avantaje	Dezavantaje
Ultrasonografia dublă	Necostisitoare, reproductibilă, noninvazivă	Inconvenientul de a detecta trombul sub claviculă în vena subclaviculară.
Computer tomografia (CT)	Compresiune vasculară din exterior; poate descrie trombul central.	Necesită substanță de contrast; nevalidată în totalitate.
Rezonanța magnetică (MRI)	Detectează trombul central cu acurateţe; bună evaluare a colateralelor.	Nepotrivită pentru pacienții cu implanturi metalice sau pacemakere; claustrofobie.

Flebografia nu este practicată la femeia gravidă, pacienți alergici la iod, în caz de insuficiență renală, hepatică, etc. (21).

Această tehnică invazivă de explorare a circulației venoase se poate solda cu urmatoarele complicații: tromboflebită post flebografie (sau agravarea celei preexistente, cca 1%); infecție la locul puncției; extravazarea contrastului, ce poate duce la necroze tisulare locale (22).

TRATAMENT

Obiectivele principale ale tratamentului TVP sunt prevenirea embolismului pulmonar şi a sindromului posttrombotic. Pentru a realiza aceste obiective, tratamentul ideal ar trebui: 1) să reducă masa trombusului; 2) să mențină structura şi funcția sistemului venos a membrului afectat, inclusiv structura şi funcția valvulelor venoase; 3) să prevină embolizarea trombilor în plămâni. Aceste obiective sunt parțial atinse de tratamentul anticoagulant şi într-un mod aproape maximal de cel trombotic (23).

Anticoagularea este esențială în managementul TVP a membrelor superioare. Scopul este de a preveni eventuala propagare a trombului şi de a menține permeabilitatea venelor colaterale (23). Anticoagulantele nu lizează trombusul, ci previn extinderea acestuia, ameliorează simptomele acute şi indirect previn embolismul pulmonar, deci mortalitatea prin această complicație. Trombii venoşi sunt lizați parțial prin activitatea trombolitică naturală sau se epitelizează, dar structurile valvulare venoase rămân afectate, permițând apariția secundară a sindromului posttrombotic la aproximativ 50% din bolnavii cu TVP proximală. Astfel, terapia anticoagulantă este esențială în reducerea extensiei şi complicațiilor imediate ale TVP, dar este relativ puțin eficace în prevenirea sechelelor tardive, în special a sindromului posttrombotic (24).

Mai multe studii au validat utilizarea heparinei nefracționate cu greutate moleculară mică şi chiar a inhibitorului trombinei în terapia TVP ca o punte către terapia cu warfarină (22). Durata standard este de 6 luni de anticoagulante orale (21, 22, 24).

Agenții trombolitici lizează trombii venoşi prin activarea enzimei plasmatice inactive, plasminogen, în plasmină activă.

Aceasta degradează fibrina din trombus sau din cheagul hemostatic, în peptide solubile. De asemenea plasmina circulantă degradează fibrinogenul solubil, şi în parte, alte proteine plasmatice (21).

Pacienţii tineri şi activi cu sindrom Paget-Schroetter au un risc crescut pentru dezvoltarea consecinţelor pe termen lung (impotenţă funcţională) şi sunt de obicei trataţi mult mai agresiv decât utilizarea doar a anticoagulării convenţionale (21, 24, 25). Tromboliza restabileşte permeabilitatea venoasă rapid, minimizând prejudiciul endoteliului vascular şi reducând riscul complicaţiilor pe termen lung; aceasta este în special valabil pentru sindromul post-trombotic, caracterizat printr-o durere şi tumefacţie cronică a braţului şi mâinii. Contrar, tromboliza este rar utilizată pentru tratamentul TVP a extremităţilor inferioare deoarece aceşti pacienţi nu sunt, în general, suficient de preocupaţi de potenţialul risc al tumefacţiei cronice a piciorului. Cei mai buni candidaţi pentru tromboliză sunt tinerii, de altfel pacienţi sănătoşi cu TVP a membrelor superioare primară, pacienţii cu sindromul venei cave superioare simptomatic şi cei cărora li se impune păstrarea unui cateter venos central (25).

Contraindicaţiile includ sângerarea activă, intervenţiile neurochirurgicale în ultimele 2 luni, un istoric de infarct hemoragic, hipersensibilitate la agentul trombolitic şi intervenţii chirurgicale în ultimele 10 zile. Riscurile efectelor sistemice ale trombolizei sunt minimalizate folosind tromboliza dirijată prin cateter (26). Consensul general este de a folosi activatorul tisular de plasminogen obţinut prin metoda recombinării (rt-PA) sau urokinaza (23).

Intervenţia mecanică cu Angiojet poate evacua o mare cantitate a trombusului şi, în acest fel, limitează doza şi durata terapiei trombolitice (27). Pentru a preveni depunerea de fibrină în jurul cateterului în timpul tratamentului cu trombolitice, heparina este administrată în paralel. (20).

Dacă compresia venoasă extrinsecă provoacă PSS, majoritatea chirurgilor vasculari pledează pentru corecţia precoce a anatomiei (20, 26), care poate include rezecţia primei coaste şi/sau a claviculei, în funcţie de părţile implicate.

Arhiva spaniolă RIETE Registry în care sunt înscrişi pacienţii cu TVP sau EP, evidenţiază că pacienţii cu TVP a braţului prezintă un risc crescut de evenimente mixte (TVP recurentă, embolie pulmonară simptomatică sau sângerări masive) (OR = 3; 95% CI, 1,4-6,4) odată cu înaintarea în vârstă, cu apariţia neoplasmului sau dacă au prezentat la internare EP simptomatic (28).

Un studiu efectuat în perioada ianuarie 1997 - ianuarie 2007, la Departamentul de Chirurgie Vasculară al University School of Medicine, St. Louis, Washington, a evidenţiat că durata totală a conduitei terapeutice a fost semnificativ corelată cu intervalul de timp cuprins între diagnosticul venografic şi intervenţia chirurgicală ($r = 0,820$; $p < 0,001$), fiind mai lung la pacienţii cu simptome persistente ($p < 0,05$) sau retromboză înainte de indrumarea către medicul specialist chirurg ($p < 0,01$). Astfel, evoluţie favorabilă s-a datorat abordării multidisciplinare (29).

Un studiu efectuat la Departamentul de Chirurgie Cardiotoracică al Baylor University Medical Center, Dallas, Texas a demonstrat că stenturile intravenoase (IS) sunt contraindicate pacienţilor cu tromboză a venei axilare şi/sau subclaviculare (sindromul Paget-Schrotter). (30).

Un studiu efectuat în cadrul Departamentului de Cardiologie Interventională, University of Minnesota Medical School,

Minneapolis, USA, în perioada iulie 1985 - iunie 2006, evidentiază importanța tratamentului de urgență în sindromul Paget-Schrotter, constând în tromboliza imediată şi operație după evenimentul acut (31).

Unul dintre studiile efectuate în România despre tromboflebita profundă a membrului superior, publicat în 2006, evidențiază importanța terapiei anticoagulante precoce concomitent cu terapia adjuvantă în vindecarea fără sechele (32).

O echipă de medici germani de la Universität des Saarlandes, Hamburg a elaborat un studiu țintit pe circumstanțele în care tromboza primară a extremității superioare poate fi proclamată şi compensată de către societățile de asigurări fie ca accident de muncă, fie ca boală profesională. Concluzia a fost că sindromul Paget-Schroetter este o boală profesională si există relație între istoricul profesional şi manifestarea trombozei, eforturile fizice crescute sau mişcările din timpul activităților de la locul de muncă (33). În România, tromboflebita de efort a membrelor superioare este inclusă în lista bolilor profesionale cu declarare, cercetare şi evidență obligatorie, conform H.G. 1425/2006.

EVOLUȚIE

Pacienții simptomatici netratați vor dezvolta, datorită obstrucției venoase, o incapacitate pe termen lung având drept rezultat o pierdere importantă a productivității ocupaționale şi a calității vieții. Din acest motiv, cateterizarea precoce în scopul trombolizei, urmată de anticoagulare şi intervenție chirurgicală sunt recomandate în majoritatea literaturii recente. Tromboliza este cea mai comună formă de tratament, urmată de chirurgie, dacă se impune. Majoritatea literaturii susține o abordare multimodală, dar nu există un consens definit al managementului. Este nevoie de studii clinice randomizate care să stabilească cele mai sigure şi eficiente anticoagulante şi să definească durata optimă a tratamentului după tromboliză (34).

3. Clinica de Gastroenterologie şi Hepatologie, SUU Elias

LOCALLY ADVANCED OR METASTATIC GASTRIC CANCER - NEW THERAPEUTIC SOLUTIONS (Abstract): Gastric cancer represents a major health problem worldwide. It is often diagnosed at an advanced stage, because screening, which would help an early detection is performed only in Japan. Gastric cancer rates may be decreased by reducing smoking and alcohol consumption and by increasing the number of fresh fruits and vegetables eaten. Eradication of Helicobacter pylori may also decrease gastric cancer incidence. Seventy-five percent of the patients are diagnosed in unresectable stage. They represent a challenge for clinicians as they have to choose between a strictly supportive approach or to expose patients to the side-effects of a potentially ineffective treatment. The treatment of advanced gastric cancer is essentially palliative. Therapy's main aim in this common group of patients with unresectable or metastatic disease is to achieve good symptomatic control, to improve quality of life, to avoid tumor progression and to prolong survival. **Key words**: ADVANCED GASTRIC CANCER, CHEMOTHERAPY, RETROSPECTIVE STUDY

Cancerul gastric constituie a doua cauză de mortalitate prin cancere în întreaga lume, cu toate că incidenţa globală este în scădere. Se estimează că în SUA, în anul 2009 au fost 21.130 cazuri noi şi 10.620 decese datorate neoplaziilor gastrice (1). Vârsta medie la diagnostic este de 71 ani în SUA şi o decadă mai devreme în Japonia (2).

Cauzele includ factori genetici şi factori din mediu. Din punct de vedere genetic sunt descrise: mutaţia genică p53, pierderea heterozigoţiei LOH a locusului APC, deleţia sau supresia genei FHIT etc. Factorii din mediu includ: dieta bogată în sare, nitraţii; produsele afumate, fumatul, infecţia cu *H. pylori* şi virusul Epstein Barr (EBV), obezitatea, consumul cronic de băuturi alcoolice, intervenţiile chirurgicale gastrice anterioare (3).

Cancerul gastric precoce este asimptomatic în 80% din cazuri (4). Când simptomele apar ele tind să mimeze ulcerul peptic. Cancerul gastric avansat este însoţit de scădere ponderală, dureri abdominale, greaţă, vărsături, saţietate precoce, disfagie, melenă, obstrucţie pilorică.

Diagnosticul este stabilit prin utilizarea de primă intenţie a endoscopiei digestive superioare (acurateţe diagnostică de 95%). În Japonia şi alte state cu prevalenţă mare se folosesc cromoendoscopia, NBI (narrow band imaging), endoscopia cu magnificaţie pentru detecţia cancerului gastric precoce.

Metodele de stadializare includ: ultrasonografia endoscopică, tomografia computerizată, rezonanţa magnetică, PET scan.

Prognosticul cancerului gastric rezecabil este influenţat de invazia peretelui gastric şi de implicarea ganglionilor limfatici regionali.

TRATAMENT

1. TRATAMENTUL CHIRURGICAL ŞI TERAPIA ADJUVANTĂ PERIOPERATORIE

Această opţiune reprezintă singura modalitate cu viză curativă a cancerului gastric. În Japonia este folosită cu succes rezecţia endoscopică mucozală pentru leziuni T1 de dimensiuni reduse. De asemenea, este folosită cu succes rezecţia gastrică laparoscopică pentru cancere precoce şi leziuni submucozale.

Cele 2 metode chirurgicale generale utilizate pentru cancerul gastric localizat sunt gastrectomia totală şi subtotală cu disecţia limfonodulilor regionali.

Rolul chimioterapiei adjuvante în CG este încă în curs de elucidare. Într-un studiu publicat în 2001, Lowy a demonstrat superioritatea radio-chimioterapiei (RT 45Gy + 5-fluorouracil 300 mg/m^2) urmata la 4-6 săptămâni de rezecţie chirurgicală şi radio-chimioterapie intraoperatorie (10 Gy). 11% din pacienţi au avut răspuns complet, iar răspunsul parţial a fost obţinut la 63% (5).

Într-un recent studiu de fază III, Stahl şi colaboratorii au constatat o creştere a răspunsului complet (15,5% vs. 2%) şi a răspunsului ganglionar (64,4% *vs*. 37,6%) în cazul pacienţilor cu adenocarcinom de joncţiune esogastrică local avansat, la care rezecţia chirurgicală a fost precedată de radiochimioterapie (cisplatin, 5- fluorouracil + 15-17 Gy) respectiv numai chimioterapie. Rata de supravieţuire la 3 ani a crescut de la 27,7% la 47,4% în cadrul braţului cu radiochimioterapie (6).

Chimioterapia adjuvantă intraperitoneală necesită evaluare şi investigaţii suplimentare în cadrul unor trialuri randomizate.

Trialul MAGIC (faza III) a evidenţiat faptul că în cazul pacienţilor cu adenocarcinoame esofagiene distale sau gastrice, chimioterapia perioperatorie (3 cicluri preoperatorii şi 3 postoperatorii constând în epirubicin, cisplatin şi 5- fluorouracil - schema ECF respectiv ECX când s-a înlocuit 5- fluorouracil cu xeloda) poate duce la descreşterea dimensiunilor tumorale şi la o îmbunătăţire semnificativă a progresiei şi a supravieţuirii globale de la 20 luni la 24 luni în favoarea braţului cu chimioterapie (7). În Marea Britanie şi în alte state europene, acesta este standardul de tratament la pacienţii cu cancer gastric rezecabil.

2. TRATAMENTUL ÎN CANCERUL GASTRIC LOCAL AVANSAT ŞI METASTAZAT

În practica zilnică suntem confruntaţi cu cereri contradictorii ale pacienţilor în ceea ce priveşte eficacitatea tratamentului (care este bineînţeles şi agresiv), dar şi menţinerea unei calităţi a vieţii corespunzătoare. CG este unul din cancerele care evoluează cu cele mai multe complicaţii generale: fracturi, tromboembolii, dureri, scădere în greutate, anorexie şi în plus multiple complicaţii digestive: ocluzii intestinale, perforaţii, sângerări şi disfuncţii viscerale motorii.

În acest moment în care "medicina bazată pe dovezi" reprezintă standardul de aur pentru o bună practică medicală şi există din plin literatură (review) publicată în jurnale respectabile, doar puţine din ele se referă la strategia din boala incurabilă, adică stadiul IV. De asemenea în practica zilnică, de cele mai multe ori, ne conducem în alegerea unui tratament după experienţa personală şi după posibilităţile centrului, şi mai puţin după datele din literatură.

În acest stadiu, scopul terapiei este reprezentat de un mai bun control al simptomatologiei, ameliorarea calităţii vieţii, întârzierea progresiei tumorale şi prelungirea supravieţuirii (8).

Modalităţi de tratament:

- stentare enterală în caz de obstrucţie; 7-22% din pacienţi însă necesită reintervenţii (9),
- rezecţia gastrică paliativă fără limfadenectomie D2 aduce o uşoară creştere a supravieţuirii comparativ cu lipsa gas-

TABELUL I
Monochimioterapia în cancerul gastric

Schema	RR	Observaţii
5- fluorouracil	21%	
Mitomicină C	30%	Mielotoxicitate tardivă (8 săpt.)
Doxorubicină	17%	
Cisplatin	19%	Lacave et al.
Taxani	17-29%	Alternativă la linia I
UFT (uracil + ftorafur)	28%	Adm. orală. RA: greaţă, vărsături, diaree
Capecitabină	19,4%	Adm. orală
Irinotecan	19%	
S1	49%	Utilizat doar in Japonia in prezent

TABELUL II
Regimuri de polichimioterapie folosite în cancerul gastric local avansat/metastazat

Schema	RR	Suprav. medie	Observaţii
FAM (5-FU, doxorubicin, mitomicină C)	40%		Standard până în 1980
FAMTX (5-FU, doxorubicină, leucovorin, metotrexat)	41%	42 săpt.	Standard în 1990
ECF (epidoxorubicin, cisplatin, 5-FU)	*71%*	*8,9 luni*	*Standard actual – toxicitate redusă*
EAP (etoposid, doxorubicin, cisplatin)	64%	9 luni	Posibile decese datorate toxicităţii
ELF (etoposid, 5-FU, leucovorin)	53%	11 luni	
Oxaliplatin, 5-FU, leucovorin	54%	11,4 luni	Efecte adverse: neutropenie, anemie
EPFL (epirubicin, cisplatin, 5-FU, leucovorin)	62%	8 luni	Mielotoxicitate importantă
XP(xeloda,cisplatin)	55%		Toxicitate scazuta grd3/4
Docetaxel, cisplatin	53%		Neutropenie 68%

trectomiei (9),

- by-pass gastric paliativ – gastrojejunostomă laparoscopică (9),
- radioterapia paliativă – determină amendarea sângerărilor locale şi a durerii date de invazia tumorală, fără a ameliora supravieţuirea,
- imunoterapia antineoplazică – nespecifică (BCG viu) şi specifică (antigeni tumorali sterilizaţi, IL, tulpini bacilare atenuate, anticorpi monoclonali etc.) – sunt metode aflate în studiu,
- chimioterapia paliativă aduce un plus de supravieţuire de 3-9 luni faţă de BSC. Trialurile randomizate care au comparat monoterapia (tabelul I) cu regimurile combinate au arătat rate de răspuns crescute pentru polichimioterapie, cu o rată de supravieţuire aproximativ egală.

În prezent, monoterapia nu mai este recomandată în managementul cancerului gastric local avansat/metastazat. Multe din trialurile care evaluează monochimioterapia sunt mici şi necontrolate, făcând dificilă elaborarea unor concluzii clare în ceea ce priveşte eficienţa. Metaanaliza a 11 trialuri randomizate care au cuprins un număr de 1472 pacienţi, din care 8 s-au desfăşurat înainte sau în anii 1990, a relevat faptul că terapia cu un singur agent citostatic nu este recomandată

TABELUL III
Polichimioterapia de linia a II-a

Tratament	Nr. pac.	RR	Timp până la progresia bolii	Suprav. globală (luni)
Docetaxel 75 mg/m² la 3 săpt. (16)	49	16%	2,5	8,3
FOLFIRI (17)	38	29%	3,7	6,4
Irinotecan 125 mg/m² z1,8,15 – la 4 săpt. (18)	37	20%	2,6	5,2
Irinotecan 160 mg/m² + Docetaxel 65 mg /m² (19)	49	20%	2,7	8,9

în CG local avansat/metastazat.

Trialul REAL 2 a dovedit noninferioritatea combinaţiei oxaliplatin+capecitabină faţă de 5-FU (fluorouracil) + cisplatin, supravieţuirea fiind aproximativ egală în cele 4 braţe ale studiului (ECX /EOX/ECF/ ECX) (10).

În acelaşi timp, la Royal Marsden Hospital din Londra a fost propus regimul ECF cu o perfuzie continuă de 5FU în doză mică, cu o rată de răspuns de 71% (din care 12% răspunsuri complete). Comparativ cu FAMTX, într-un studiu de fază III, ECF-ul a determinat o rată de răspuns de 45% vs 21% (p=0.0002) şi un timp mediu până la progresie de 7,4 luni *vs* 3,4 luni, cu o supravieţuire globală de 8,9 luni *vs* 5,7 luni (p=0,00090). Astfel ECF a devenit standardul în practica zilnică (Tabel II).

Într-un studiu coreean de fază III (xeloda 1000 mg/m²/zi, z1-14 + cisplatin 60-80 mg/ m², z1, repetat la 3 săptămâni) efectuat pe 42 pacienţi, rata de răspuns a fost de 54,8%, timpul mediu de progresie fiind de 6,3 luni şi fără efecte adverse importante (11).

Trialul randomizat multicentric ML 17032, la care au participat 13 ţări, a comparat eficacitatea şi profilul de siguranţă a combinaţiei Xeloda/Cisplatin (XP) cu regimul clasic 5FU/Cisplatin (FP). În braţul XP s-a administrat Xeloda 1000 mg/m² p.o. zilele 1-14 ţi cisplatin 80 mg/m² i.v. ziua 1, iar în bratul FP s-a administrat 5FU 800 mg/m²/zi perfuzie continua zilele 1-5 şi cisplatin 80 mg/m² i.v. ziua 1, la 21 zile interval. Rata de răspuns a fost superioară în braţul XP *vs* FP (41% *vs* 29%, p=0.03), iar supravieţuirea generală mediană (10.5 *vs* 9.3 luni) şi cea fără semne de boală (5.6 *vs* 5.0 luni) . Cele mai importante efecte adverse de grad 3-4 (XP *vs* FP) au fost neutropenia (16% *vs* 19%), vărsăturile (7% *vs* 9%), stomatita (2% *vs* 7%), diareea (5% *vs* 5%) şi anemia (5% *vs* 3%). Rezultatele susţin posibilitatea înlocuirii 5FU perfuzabil cu Xeloda în cancerul gastric avansat.

În ultimii ani au fost folosiţi pentru tratarea cancerului gastric local avansat sau metastazat: taxani (paclitaxel şi docetaxel), inhibitori de topoizomerază I (irinotecan), derivaţi noi de platină (oxaliplatin). Per ansamblu, folosirea acestor droguri noi în studiile de fază II a dus la o rată de răspuns de 65%, fără a se înregistra o creştere globală a supravieţuirii (circa 10 luni) (12,13,14).

Supraexpresia receptorului factorului de creştere epidermală EGFR, a receptorului factorului de creştere endotelială VEGFR şi a HER2 a fost asociată cu un prognostic mai prost. În trialuri clinice, trastuzumabul (anticorp anti-HER2), bevacizumabul (anticorp anti-EGFR), cetuximabul (anticorp anti--VEGFR) au fost testaţi în combinaţii cu diverse citostatice.

Studiul ToGA (15) care a comparat trastuzumabul (la pacienţii HER2 pozitivi) în combinaţie cu cisplatin + 5-FU vs. cisplatin + 5-FU a evidenţiat superioritatea regimului care a asociat trastuzumabul, supravieţuirea mediană fiind de 13,5 *vs*. 11,1 luni. Acest

TABELUL IV
Schemele de polichimioterapie folosite

Linia I de tratament:	
• *MAYO*	*25 pac.*
• *5-FU + CDDP*	*22 pac.*
Linia II de tratament	
• *Capecitabină + CDDP*	*5 pac.*
• *Taxol + CDDP*	*7 pac.*

fapt a dus la înregistrarea schemei ca standard de tratament la pacienţii cu cancer gastric local avansat/metastazat HER2 pozitivi.

Polichimioterapia de linia II a (tabelul III) – trialurile de fază II au arătat o rată de răspuns joasă la pacienţii selectaţi care pot beneficia de chimioterapie de linia a II-a. Nu există trialuri de fază III pentru chimioterapia de linia a II-a.

Există în momentul de faţă mai multe trialuri în desfăşurare :

(a) ST03 – MAGIC B : adenocarcinom gastric rezecabil sau Type III OGJ (3 cicluri ECX - epidoxorubicin, cisplatin, xeloda/chirurgie/3 cicluri ECX *vs.* 3 cicluri ECX + bevacizumab/chirurgie/3 cicluri ECX + bevacizumab) (20),

(b) CRITICS : adenocarcinom gastric rezecabil sau Type III OGJ (3 cicluri ECX/ chirurgie/3 cicluri ECX *vs.* 3 cicluri ECX/ chirurgie/ECX + RT 45Gy) (21),

(c) REAL3 : adenocarcinom avansat netratat sau carcinom nediferenţiat de esofag, joncţiune eso-gastrică sau stomac (EOX – epidoxorubicin, oxaliplatin, xeloda vs. EOX + panitumumab) (22).

Regimuri de chimioterapie folosite în cancerul gastric :

- **FAM** : 5FU 600 mg/m^2 iv z1,8,29,36+ Dox 30mg/m^2 iv z1,29+Mit C10mg/m^2 iv z1 repetat la 8săpt (12),
- **FAMTX** : 5FU 1500 mg/m^2 iv z1 la 1h după MTX+Dox 30 mg/m^2 iv z15+ MTX 1500 mg/m^2 iv z1 + leucovorin 15 mg/ m^2 po administrat la fiecare 6h,12 administrări, începând la 24 h după MTX, cu hidratare şi alcalinizarea urinii anterior de administrarea MTX, repetat la 28 zile (12),
- **ECF** : Epidoxorubicin 50 mg/m^2 iv z1 +Cisplatin 60 mg/m^2 iv z1, repetat la 3 săpt pentru max 8 cicluri +5FU 200 mg/ m^2 în pev continuă - 6 luni (23,)
- **ECX** : epidoxorubicin 50mg/m2ivz1+Cisplatin 60mg/m2 iv z1+Xeloda 2000mg/ m^2, po,z1-14, repetat ciclul în z22 (13)
- **DCX** : docetaxel : 60mg/m^2 iv z1+cisplatin 60 mg/m^2 iv z1+xeloda 2000 mg/ m^2, po z1-14 repetat la 3 săpt (11),
- **EOX** : epidoxorubicin 50 mg/m^2 iv z1 + Oxaliplatin 130mg/m^2 iv z1+Xeloda 2000 mg/m^2, po, z1-14, repetat ciclul în z 22,
- **EOF** : epidoxorubicin 50 mg/m^2 iv z1+ Oxaliplatin 130mg/m^2 + 5FU 200 mg/m^2 în pev continuă 6 luni, repetat ciclul în z22,
- **DC** : docetaxel 75 mg/m^2 iv,z1+cisplatin 75 mg/m^2 iv, z1, repetat la 3 săptămâni (14),
- **DCF** : docetaxel 75 mg/m^2 iv, z1+cisplatin 75 mg/m^2 iv, z1+5FU 200 mg/m^2 pev prelungită timp de 2 săptămâni, repetată la 3 săptămâni (14),
- **DCF(V325)** : docetaxel 75 mg/m^2 iv, z1+ cisplatin 75 mg/m^2 iv, z1+5FU 750 mg/m^2, z1-5 repetat la 3 săptămâni,
- **CF** : cisplatin 100 mg/m^2, z1+5FU 1g/m^2 în pev continuă z1-5, repetat la 4 săptămâni,
- **ILF** : CPT-11 80 mg/m^2 urmat de LV 500 mg/m^2 în 2 ore urmat de 5FU 2g/m^2

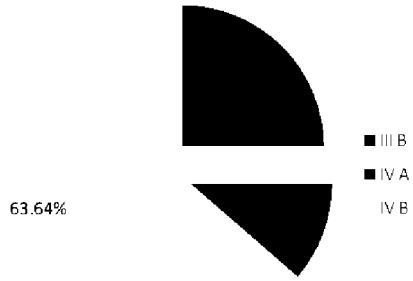

Fig. 1. Repartiţia pacienţilor în funcţie de stadiul bolii

pev de 22 ore, săptămânal timp de 6 săptămâni,

- **ECD**: epirubicin 50mg/m^2 iv, z1+docetaxel 60 mgiv/m^2, z1+cisplatin 60 mg/m^2 iv, z2, repetat la 3 săptămâni,
- **XELOX**: xeloda 2500 mg/m^2, z1-14 + oxaliplatin 85 mg/m^2, z1, repetat la 21 zile,
- **CPT-11**: 70mg/m^2 iv, z1, 15+ cisplatin 80 mg/m^2, z1, repetat la 4 săptămâni,
- **PCF**: paclitaxel 175 mg/m^2 iv, z1 + cisplatin 20 mg/m^2, z1-5 + 5FU 750mg/m^2 pev, z1-5, repetat la 3 săptămâni.

În cadrul Departamentului de Oncologie Digestivă a Institutului Clinic Fundeni am efectuat un studiu retrospectiv în perioada 2003-2004, asupra unui număr de 47 pacienţi cu cancer gastric avansat sau metastazat, confirmat histopatologic. Ne-am propus să urmărim toxicitatea schemelor chimioterapice utilizate, supravieţuirea globală şi supravieţuirea fără semne de boală.

Din totalul de 47 pacienţi, un procent de 25% prezentau cancer gastric local avansat, 63,64% stadiul IVA metastatic, respectiv 11,36% stadiul IVB metastatic (Fig.1).

Din punct de vedere histopatologic, toţi cei 47 de pacienţi au prezentat histologie de adenocarcinom.

Vârsta medie a lotului nostru a fost de 57 ani (28-76 ani), mediul de proveniență al pacienţilor fiind predominant urban (41 *vs*. 6 rural). 77% din pacienţi au suferit intervenţie chirurgicală cu viză paliativă, în timp ce la 23% nu s-a intervenit chirurgical.

33 pacienţi (70,2%) prezentau determinări secundare în momentul diagnosticului; 21 pacienţi (44,6%) aveau o singură metastază (12pacienţi – hepatică, 2pacienţi – pulmonară, 5 pacienţi – peritoneală, câte 1 pacient – ovariană, respectiv osoasă; 8 pacienţi aveau 2 localizări de metastaze, iar la 4 pacienţi au fost întâlnite peste 3 localizări de metastaze.

Schemele de polichimioterapie utilizate la aceşti pacienţi sunt prezentate în tabelul IV.

Din punct de vedere al efectelor secundare hematologice, pancitopenia a fost întâlnită predominant în cazul pacienţilor trataţi cu 5FU+CDDP. Toxicitatea digestiva (greaţă, vărsături, diaree, stomatită) a fost întâlnită în ambele braţe, cu o rată mai ridicată în subgrupul celor care au primit 5FU+ CDDP, alopecia urmând aceeaşi tendinţă.

De asemenea, toxicitatea renală a predominat în braţul celor trataţi cu CDDP şi 5-FU.

Supravieţuirea fără semne de boala a fost în medie de 6,31 luni (4,89-7,72 luni), iar cea globală calculată prin metoda Kaplan-Maier a fost în medie de 11 luni (7-14 luni).

Concluzii: (a) chimioterapia sistemică prelungeşte supravieţuirea globală; (b) menţinerea unui status de performanţă corespunzător a făcut posibilă administrarea liniei a II-a de tratament, ceea ce va creşte şi mai mult supravieţuirea globală; (c) probabil administrarea noilor agenţi chimioterapici va creşte nu numai ratele de răspuns, dar şi supravieţuirea globală, permiţând obţinerea unor remisiuni de lungă durată.

EDITORIAL

COMPLICATIONS IN LAPAROSCOPIC SURGERY KEEP HAVING HIGH INCIDENCE

Unfortunately, Complications in Laparoscopic Surgery happen, and the fact is that they keep having high incidence, despite all interest and "calls for attention". As some consequences can be important, considering the sequels they may cause, the interest for understanding how they happen and the reasons why they show keeps having a high interest.

Nowadays, a very used term related with these problems is "Precision Surgery". As a matter of fact, it is, a summary of the kind of practice we all do, mostly, if not in all cases: performing surgery with utmost care and attention, step-by-step.

Another issue regarding these problems, is that it is also very difficult to convince surgeons to perform "better"; this is the kind of surgery every surgeon is convinced he (or she), "is already performing at "TOP QUALITY".

As a matter of fact, this happens in every case of surgery where the surgeon is more active, using it most commonly, and where he (or she) thinks they "excel".

Using, just as an example, the Iatrogenic lesions of the biliary tract, we can realize that, already in 1944, the great surgeon Grey-Turner was writing in the *Lancet*: "CBD lesions are, almost always, a result of an accident during surgery and, therefore, it can only be attributed to the surgical profession. These lesions cannot be a normal operative risk…"; (1) and A. R. Moossa, in a personal communication said: "we can generalize the 3 dangers of biliary lesions as:

1. Dangerous disease, like late acute cholecystitis, portal hypertension,
2. Dangerous anatomy, considering there are anomalies in 10-15% of cases,
3. Dangerous surgery, when the surgeon performs with technical deficiencies.

We can understand the appearance of complications, following the so-called Reason's Model of complications, or events". This is also known as the Swiss Cheese model (fig. 1). Considering a series of slices of swiss cheese, when all holes of it are in a line, meaning that we face a "lining" of possible errors or "mishaps", then, all conditions are arranged for the complication to happen.

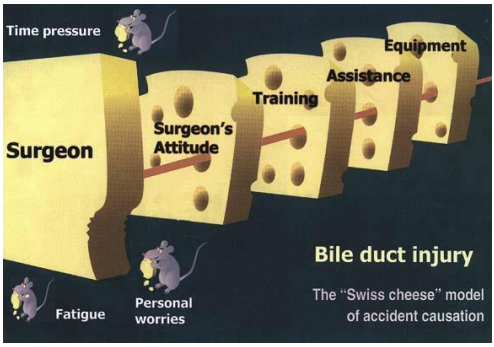

Fig. 1. The "Swiss Cheese" model of accident in laparoscopy

If we compare errors leading to complications in surgery, with the ones happening in high technology industries, we can see some similarities. They are based, mainly, in four orders of facts: Technical failures, Not following established rules, Ignorance of certain aspects of the process and Visual failures or misguidance for what one is

seeing.

There are certain General Factors, explaining these facts, and the General Etiology of Complications in Laparoscopic Surgery: starting with some technical situations, we have, inadequate placement of trocars, bad field exposition, bad light, bad anesthesia, surgeon (or team)'s inexperience, surgeon (or team)'s tiredness, lack of knowledge of eventual anomalies, patient issues, disease itself, inappropriateness (somehow) of the surgeon and/or surgical team, inappropriateness of the instruments..

Some points should be followed to minimize complications.

To start, let's not simplify Indications; these should follow the Guidelines for Indications for any kind of Laparoscopic surgery, not "forcing" the indications for each proposed patient.

Just because Laparoscopic Surgery is "simpler" do not see it as a reason for widening indications.

There are other problems related with the "Learning Curve" although this might be an issue to discuss separately, if one considers the concept of "Learning Curve" by itself. To start with, the "Learning Curve" for Laparoscopic Cholecystectomy, for instance, goes well beyond 50 cases and the operating time keeps lowering till 200 cases; on another hand, the improvement in the cognitive skills to deal with difficult cases continues for more than that. This according with Voitk *et al.*, as published in the *Am J Surg*, in 2001 (2).

But the risk goes beyond "first cases"; according to Morgenstern *et al.*, in a paper published in *Am J Surg*, in 1995, in a single institution, the first 1284 cases had a rate of complications of - 0.58% the following 1143 cases had a similar rate, - 0.50% (3).

Calvete *et al.*, published a paper in 2000, in *Surgical Endoscopy*, where they made an enquiry to 1500 surgeons and realized that about 30% of the rate of Bile Duct Injuries reported by those surgeons occurred after the first 200 cases (4).

What we can summarize is that surgeon's experience does not minimize the risk.

Way *et al*., published a very good paper in *Annals of Surgery*, in 2003, showing an interesting point for causes of Common Bile Duct lesions in Laparoscopic Cholecystectomies (5).

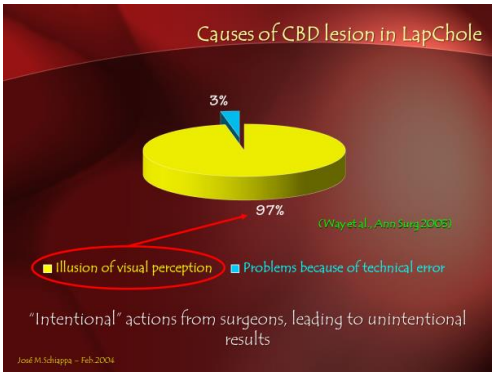

Fig. 2. Causes of Common Bile Duct lesions in Laparoscopic Cholecystectomies

This paper shows that only 3% of the causes of CBD lesions are technical; the other 97% are a result of what is called illusion visualization of reality (fig. 2). The brain, through a process called "Heuristic" shows its "laziness". As such the brain shows what it believes is the wish of the person to see. This leads to "Intentional" actions from surgeons, leading to unintentional results. We can show some examples of these processes: "Heuristic" Processes.

In this image, most people believe that they are seeing two triangles, a white one and a black one. In truth, there are no triangles at all: there are only three angles and

three "Pack Man" in such a disposition that they show the composed image one's brain processes as a composite one. This image is called - Kanizsa's Triangle (fig. 3).

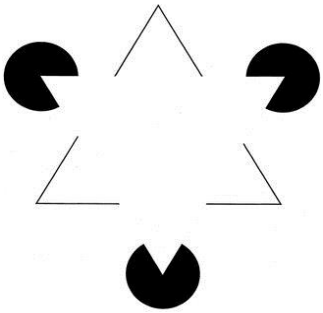

Fig. 3. Kanizsa's Triangle

Another example is the image above: depending on the first time one looks at it (and the fact that there is a mention of "first time" is because after this first viewing, it will be quite difficult to see it otherwise).

Another way of understanding "Heuristic" Processes is the watching of this turning image of a lady. Some persons will be able to see her turning Clockwise, some others turning Anti-clockwise: the authors of this image have found out that the ones seeing her turning Clockwise have a dominance in their brains, from the Right Brain, and the ones watching her turning Anti-Clockwise have a dominance from their Left Brain, as shown in the image (fig. 4). Now, turning into interpretation of this turning image: The Right Brain provides Anarchic Thinking, Intuitive ways of seeing life, Holistic, Synthetic and Subjectivity; while the dominance of the Left Brain, provides Logic Thinking, Sequential, Rational thinking, Analytic views, and Objectivity. Many problems arise, in fitting their ways of thinking, to the ones who can see the image turning both ways, as it may happen to a 5% number of persons, seeing it happen sequentially.

Fig. 4. "Heuristic" Process

A totally different aspect is Instrument Problems; of these we can consider two main ones: Use of Electrosurgery; when it is used too often for too long periods. The hook in general is very difficult to control, despite considerations by surgeons that in their hands all instruments are safe; when used to cut some structures, hooks can cut suddenly, being left free and almost uncontrollable and being able to transmit its heat to the organ it touches. Another issue is the fact (often forgotten) that all heating devices, including most of the thermal sealing and cutting instruments go to very high temperatures (up to 300ºC) and they take about 30 seconds to come back to zero. Very frequently surgeons are seeing using the instrument immediately after a "cutting session", to set aside or to dissect other organs.

Another situation arises from some disturbance in the electrical protection of the instrument, which usually is not visible, or looked for. One point more regards the use of the wrong instrument for a certain task; it is to be noted that any surgeon shall not be carried away, showing one's "abilities"

with every type of technology.

We can say that Lesions in Laparoscopic Surgery are serious lesions, but can be avoided (or, at least, minimized) by: a cautious approach when dealing with any kind of Laparoscopic surgery (1, 6).

Keeping a very liberal policy of conversion or asking for specialized help when facing any unexpected intra-operative problems and considering that by its specificity they should always be dealt with by experienced teams in reference centers, especially if the idea is to solve the problem still with a Laparoscopic approach.

Another precaution measure is to always use Prevention attitudes, and these may (or should) include: surgical access always adapted to patient's morphology, which can be different - do not use a "standard" approach; get always a good exposure of the surgical area and - again, always - get a good identification of structures, before any definitive measure (1,7).

Appropriate and correct dissection always, identifying all structures, clamp any vascular pedicles if in face of any big hemorrhage. Because of the reasons previously mentioned, take great care with the use of electrosurgery; do always use the highest human and surgical good sense (despite being what all surgeons say they do); have adequate knowledge of the local anatomy and of eventual anomalies. One very important point, often forgotten for several reasons is "When in doubt, stop and re-evaluate" and keep always keep a humble attitude.

Any surgeon must be aware of situations and of his (or hers) capacities; as such, every time one thinks it is advisable, ask for help...

Summarizing, one shall always be very aware of some Basic Rules (not to forget) (1, 8):

- No Surgeon is "protected" against this problem.
- Correct and complete training in Laparoscopy is mandatory.
- The leading Surgeon is responsible for the adequacy and quality of all the equipment and adequacy and quality of the team.
- THERE WILL BE MANY OPPORTUNITIES FOR DISASTER "...those who fail to remember the past, are doomed to repeat it..." (Santayana)

Tips for Safe Cholecystectomy (1, 8):

- Urinary bladder evacuated just before anesthesia and surgery;
- General anesthesia;
- Open insertion of first cannula;
- All instruments must be introduced, operated and removed under vision;
- Fundus retracted upwards towards right shoulder;
- Gall bladder neck retracted down and out;
- Cystic lymph node is an important landmark - keep to its right;
- No cautery in Calot's triangle - it should be used in gall bladder bed only;
- Clipping of the cystic duct flush with the common bile duct is not required;
- It is safer to leave a few mm of cystic duct than to encroach even l mm on the common bile duct;
- Double clips on the retained side of the cystic duct and cystic artery;
- Ligature, Haemoclip, Endoloop and stapler are useful devices to tackle a wide cystic, duct;
- Beware of wide cystic duct, long cystic duct, vertical cystic duct - it may be common bile duct;
- Very soft (normal) liver, fatty liver and cirrhotic liver can easily be injured

during retraction;

- Fundus first is a useful technique in difficult cases;
- Partial cholecystectomy is an option in case of difficulty;
- Panic should be avoided in case of bleeding;
- Pressure with a gauze or the mobilized gall bladder will control the bleeding or make it controllable;
- Desperate blinds attempt to clip or coagulate a bleeding point in a pool of blood must be avoided;
- Stumps (cystic duct/cystic artery) should be examined and re-examined for security of clips and any bile leak/bleed;
- Gall bladder bed should be irrigated and examined for any bleed/bile leak (from a cholecystic-hepatic duct);
- Presence of bile should make the surgeon stop and look for the source of bile - gall bladder or bile duct;
- Extraction of gall bladder under vision to make sure that there is no bile/stone spill;
- Spilled bile should be sucked out;
- Spilled stones should be looked for and removed;
- Cholecystectomy should not be considered a small/routine operation and should not be taken lightly/casually;
- Surgeons should avoid the temptation to get their names into books of records.

The day after cholecystectomy, the patient should be without pain, sitting up in the bed, having her breakfast and wanting to go home - vitals should be stable/ normal and abdomen soft; if not, observe the patient in the hospital for another day.

As general **conclusions**, it can be said that these are serious lesions. They can be avoided (or at least, minimized), by a cautious approach, a surgeon's liberal policy of conversion and asking for specialized help when facing unexpected intraoperative problems. No surgeon is "protected" against this problem, and correct training in laparoscopy is mandatory. These lesions, by their specificity, should always be dealt with by experienced teams in reference centers. Only this way, complications can be minimized, and quality and good outcomes guaranteed.

José M. Schiappa, M.D, Ph.D.,
Professor of Surgery
Department of Surgery,
Hospital CUF Infante Santo, Lisbon, Portugal

NEWS

ULTRASTRUCTURAL ASPECTS OF VACUOLAR DEGENERATION OF CARDIOMYOCYTES IN HUMAN ENDOMYOCARDIAL BIOPSIES

Vacuolar degeneration of cardiomyocytes is a histological finding commonly encountered during routine light microscopic examination of human endomyocardial biopsy specimens. The vacuoles appear as intracellular clear areas lacking myofibers. By itself, this finding has little diagnostic value, but may have important clinical implications when the vacuolar contents are of etiological significance (e.g., accumulation of abnormal metabolites), and the clinical importance is increased when the disease is treatable. Thanks to its great resolving power, electron microscopy can often reveal the contents of the vacuoles and lead to a correct diagnosis. It can be used to differentially diagnose lysosomal storage diseases such as Fabry, Danon, and Pompe disease, doxorubicin cardiomyopathy, mitochondrial cardiomyopathy, autophagic degeneration, and accumulation of subcellular organelles (mitochondria, lipofuscin, glycogen granules, endoplasmic reticulum, etc.) as a nonspecific finding in failing cardiomyocytes. In conclusion, observing vacuolar degeneration of cardiomyocytes under a light microscope provides little information because it does not enable one to identify the contents of the vacuoles. On the other hand, electron microscopic examination can often reveal the contents of vacuoles and lead to a correct cardiac disease diagnosis. But even under an electron microscope, the contents of vacuoles cannot always be identified, and so undiagnosed cases remain. These may be patients with novel disease entities waiting to be discovered. Considering the great diagnostic value of electron microscopic examination, the authors strongly recommend fixation of a small piece of tissue samples for electron microscopy at every endomyocardial biopsy procedure (Takemura G, Kanamori H, Okada H, Tsujimoto A, *et al*. Ultrastructural aspects of vacuolar degeneration of cardiomyocytes in human endomyocardial biopsies. *Cardiovascular Pathology* 2017; 30: 64-71).

AMBULATORY BLOOD PRESSURE MONITORING (ABPM) IN ELDERLY (Abstract). **Aim**: Comparison of blood pressure values measured by two methods. **Material and method**: 94 hypertensive patients (66 women and 28 men in relation to 2.36/1) were assessed classically and also by ABPM. For statistic evaluation we have used t – Student test, $\chi 2$ test, Pearson correlation coefficient and variation coefficient (cv%). **Results**: It shows significant differences between mean values of systolic and diastolic blood pressure obtained by the 2 methods. **Conclusions**: ABPM measured values are more accurate compared to clinic, bringing also information on pattern hypertensive therapy. **Key words:** ARTERIAL HYPERTENSION, BLOOD PRESSURE MONITORING, BLOOD PRESSURE MONITORING PARAMETERS

Hipertensiunea arterială (HTA) este considerată cea mai frecventă afecţiune în populaţie şi cu o rată scăzută de control terapeutic (~25%). In practica medicală curentă, tratamentul HTA este orientat frecvent în funcţie de valorile tensiunii arteriale (TA) obţinute manual, iar instituirea tratamentului se face în funcţie de experienţa clinicianului. Elementul esenţial pentru clasificarea HTA este nivelul tensiunii arteriale sistolice (TAs) şi tensiunii arteriale diastolice (TAd) întrucât morbiditatea şi mortalitatea cardiovasculară se află în relaţie continuă cu aceste variabile. Studiile epidemiologice au arătat că riscul de deces cardiovascular se dublează cu fiecare creştere cu 20/10 mmHg a TA, începând de la valori de 115/75 mmHg. Prin monitorizarea continuă a tensiunii arteriale (MCTA) se obţin valori exacte ale TA cu atât mai importante la vârstnici unde se întâlnesc multiple patern-uri hipertensive cu implicaţii terapeutice asupra controlului tensional .

OBIECTIV

Evaluarea hipertensiunii arteriale la vârstnici, prin utilizarea monitorizării continue a tensiunii arteriale.

MATERIAL ŞI METODĂ

Lotul a fost constituit din 94 pacienţi diagnosticaţi cu HTA, 66 femei şi 28 bărbaţi în raport F/M =2,36/1, cu vârste între 65 şi 83 ani. S-au evaluat prin MCTA: tensiunea arterială sistolică, tensiunea arterială diastolică, presiunea arterială medie, presiunea pulsului, încărcarea hiperbară şi indicele de hipertonie. Valorile maxime, medii şi minime se calculează pe 24 ore.

Sistemul de monitorizare utilizat a fost ABPM – 04 care foloseşte programul Medi-Base pentru prelucrarea statistică a datelor.

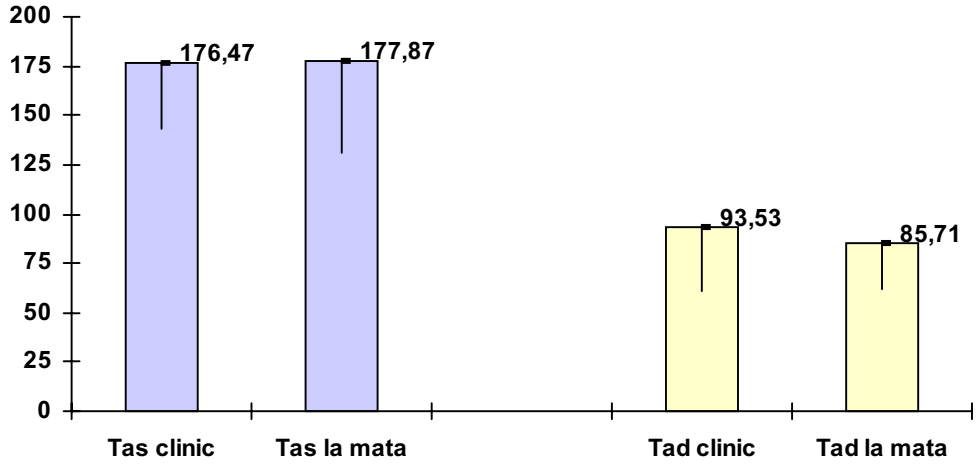

Fig. 1. Valorile medii ale TAs şi TAd.

Aparatul a fost setat pentru măsurarea TA din 15 în 15 minute în intervalul orar 6-22 şi din 30 în 30 minute nocturn (22-6). Rezultatele au fost afişate ca valori maxime, medii şi minime pe 24 h. Softul a calculat indicele diurn, indicele de hipertonie, încărcarea hiperbară pentru tensiunea sistolică, diastolică si medie.

Metode statistice aplicate: testul t-student, coeficientul de corelaţie „Pearson"(r) şi coeficientul de variaţie (CV%), prelucrate cu ajutorul funcţiilor statistice din EPIINFO şi EXCEL.

REZULTATE

Valoarea tensiunii arteriale sistolice medii măsurată clinic a fost de 176,47±26,68 mmHg, iar cea diastolică de 93,53±13,20 mmHg cu un procent de 20,2% din cazuri peste limita normală de 90 mmHg.

La monitorizarea continuă tensiunea arterială sistolică a prezentat maxime care s-au încadrat în intervalul 122 - 231 mmHg cu o medie de 177,87± 25,83 mmHg. TAd medie înregistrată a fost de 85,71± 10,61 mmHg, iar ponderea cazurilor care au depăşit limita normală a fost de 7,4% .

Tensiunea arterială medie (MAP) înregistrată a fost de 95,20±14,37 mmHg. Maximele MAP având o medie de 120,34± 22,50 mmHg iar MAP minima a avut o medie de 70,90±10,61 mmHg. MAP reprezintă măsura adevărată a debitului cardiac, definind statusul hemodinamic cu implicaţii asupra terapiei antihipertensive pentru controlul tensional specific fiecărui pacient, prin adăugarea de diuretic la pacienţii cu hipervolemie, de inhibitor al enzimei de conversie (IEC) sau un blocant de calciu la cei cu vasoconstricţie şi beta-blocant la cei cu hipertropism cardiac.

Presiunea pulsului (PP) medie înregistrată a fost de 63,12±15,46mHg, cu valori diurne cuprinse în intervalul 53 şi 153 cu o medie de 91,74±21,27 mmHg şi valori minime nocturne cuprinse în intervalul 19 la 77, cu o medie de 38,14±11,82 mmHg rezultând o afectare a sensibilităţii baroreflexe şi a balanţei autonome simpatico-parasimpatice, amplificate de amploarea fenomenelor aterosclerotice, ştiindu-se că riscul afectării cardiovasculare se asociază unei unde P peste 53mmHg (tab. I).

BP load, sau sarcina (cronică) de presiune, a înregistrat frecvente mari la TAs, în proporţie de 42,5%, în comparaţie cu TAd unde 91,5% dintre pacienţi au BP load < 100 % / 24 h (tab. II).

Sarcina de presiune de 100% denotă o creştere constantă a TA ce conduce la hiper-

TABELUL I
Diferenţe statistice ale valorilor medii a presiunii pulsului în funcţie de grupa de vârstă

Grupa de vârstă	PP medie	PP max	PP min
65-74 ani(n =65)	62,46±15,58	90,23±21,15	37,79±12,15
= 75 ani (n = 29)	64,83±15,40	95,76±21,60	39,10±11,14
t-Student	t = 0,69; p>0,05	t = 1,15; p>0,05	t = 0,51; p>0,05

TABELUL II
Distribuţia de frecvenţe a sarcinii cronice de presiune la pacienţii din lotul de studiu

BP load	TAS		TAD	
	n	%	n	%
< 100 mmHg*h/24h	54	57,5	86	91,5
100-500 mmHg*h/24h	32	34,0	8	8,5
> 500 mmHg*h/24h	8	8,5	-	-

trofie ventriculară. Din datele prezentate rezultă că un procent de 42,5% din pacienţi prezintă hipertrofie ventriculară stângă, procent confirmat şi prin ecografie.

Indexul diurn, exprimat ca raport al TAs pe interval de zi şi de noapte, a prezentat scăderi sub 10% la 43 pacienţi, între 10 şi 20% la 40 pacienţi, peste 20% la 9 pacienţi iar 2 pacienţi nu au prezentat variabilitate circadiană.

Tratament. După numărul agenţilor antihipertensivi, 45 pacienţi (47,88%) erau sub monoterapie, 27 pacienţi (28,72%) primeau biterapie, iar 22 pacienţi (23,40%) triplă asociere. După clasele de medicamente: inhibitori ai enzimei de conversie a angiotensinei (IECA) - 28 pacienţi; diuretic (D) 10 pacienţi; beta-blocante (BB) -5 pacienţi; blocante ale canalelor de calciu (BCC) -2 pacienţi; IECA+D – 1 pacient; BB+D – 3 pacienţi; BCC+D -4 pacienţi; IECA+BB+D -14 pacienţi; IECA+ BCC+D -8 pacienţi.

După tratamentul ghidat prin monitorizare continuă a pacienţilor din lotul de studiu timp de 24 de ore, tensiunea arterială sistolică medie a fost de 137,40 mmHg, iar tensiunea arterială diastolică a fost de 82 mmHg valori apropiate de cele recomandate de diferite studii (tab. III).

TABELUL III
Valorile normale ale tensiunii arteriale în funcţie de studiu

Studii	TA pe 24 ore
Ghid ABPM - BHS	<130/80
GHID OMS/ISH	125/80
Manual Meditech	130/80
Staessen	133/82

DISCUŢII

Ţinta terapeutică în HTA a vârstnicului este aceiaşi cu cea pentru pacientul tânăr adică mai mică de 140/90 mmHg dacă este bine tolerată. Pentru aceasta mulţi pacienţi necesită unul, două sau mai multe droguri antihipertensive dar reducerea sub 160 mmHg pentru HTAs izolată poate fi dificil de realizat. Tratamentul medicamentos poate fi iniţiat cu diuretice tiazidice, antagonişti de calciu, blocanţi ai receptorilor angioten-

sinei şi beta blocanţi în conformitate cu recomandările ghidurilor. Unele trialuri ce au specific tratamentul HTAs izolate au arătat beneficiul tiazidelor şi antagoniştilor de calciu, iar alte trialuri au arătat beneficiul blocantelor de receptori angiotensinici. Datorită posibilităţii crescute pentru efectele nedorite la dozele iniţiale, dozele trebuie crescute mai lent în special la persoanele foarte vârstnice. Totuşi la subiecţii de 80 de ani şi peste beneficiile terapiei antihipertensive sunt încă neconcludente. De asemenea nu există dovezi pentru întreruperea unui tratament de succes sau bine tolerat când pacientul atinge vârsta de 80 de ani să fie întrerupt.

CONCLUZII

Rezultatele studiului pun în evidenţă superioritatea controlului tensional la pacienţii cu terapie ghidată după monitorizare continuă, cu aceleaşi clase de medicamente antihipertensive dar orientată după componenta dominantă a hipertensiunii arteriale (volumul intravascular crescut, hiperinotropism sau vasoconstricţie) şi a paternului hipertensiv, micşorând numărul de cazuri de hipotensiune, de rezistenţă la tratament, de reacţii adverse ale diferitelor grupe de medicamente antihipertensive, a riscului cardiovascular total, precum si o complianţa mai bună a pacientului la tratament.

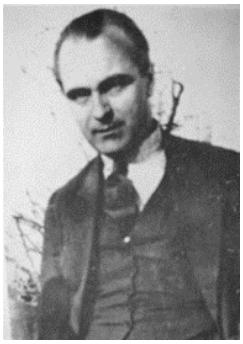
EDITORIAL

THE IAŞI SOCIETY OF PHYSICIANS AND NATURALISTS AND THE MEDICAL-SURGICAL JOURNAL DURING THE GREAT WAR

Romanian physicians – both military and civilians – were fully aware of their mission on the 27th of August with Romania's entry into the Great War joining the Entente which finally led to the unification of all provinces inhabited by Romanians. Many of those physicians were doctors and medical undergraduates from Iasi and Bucharest who unconditionally joined the army. The majority of the physicians who took part in the Great War were members of the "Sf. Spiridon" Hospital Council of Administration (Epitropy of "Sf. Spiridon") and members of the Society of Physicians and Naturalists in Iași. Some of these physicians had previously published their literary output in the main journals of the prewar period.

Among them, **Grigore T. Popa** a fresh graduate from the Faculty of Medicine in Iaşi and future professor of Anatomy and Dean of the Faculty of Medicine, future president of the Society of Physicians and Naturalists, **Mihai Ștefănescu-Galați**, founder of the Iași School of Urology, future Dean of the Faculty of Medicine, **Eugen Mironescu** future professor of Dermatology. Other physicians fought as simple soldiers or as specialists in endemic diseases (1, 2, 3).



Prof. dr.
Grigore T. Popa

Prof. dr.
Mihai Ștefănescu-Galați

Prof. dr.
Eugen Mironescu

It is but natural to feel that is our duty to identify and honor those who fought and even gave their lives to the great task of uniting all the provinces inhabited by Romanians. Among those great victors we identified some names that deserve being presented here:

Professor **Ernest Juvara** (1870-1933), the founder of the First Surgery Clinic at "Sf. Spiridon" Hospital. The gifted surgeon was mobilized in 1916 with the rank of Major and appointed to at the 4th Hospital for Evacuation that followed the 4th Army Corps at Hangu, with two complementary sections, at Bicaz and Broşteni. He moved to another fronts Piatra Neamţ, Neamţ Monastery and Botoşani. He continued to operate on the wounded soldiers' day and night.

Prof. dr. Ernest Juvara

He was promoted to the rank of colonel and was transferred to the Evacuation Hospital no. IX that followed the army corps at Mărășești. He was followed by two other celebrated surgeons: E. Christidi and Gh. Olaru. Soon he became known all over Moldavia. He was an outstanding traumatology and orthopedist who easily employed spinal anesthesia in operation rooms of the military hospitals. His team moved from hospital to hospital and performed operations that nobody ventured to think of at the time. His contributions to war surgery were included in a book: his approach to diaphysis fractures proved to be useful to say nothing of the external fixator which has been used ever since (3).

Professor **Paul Anghel** (1869-1937), also a surgeon, was mobilized in 1913 as colonel in the campaign in Bulgaria and who continued the fight until 1918.

Other physicians who had strong ties with the medical school of Iași were: dr. **George Bogdan** (1859-1930), who for the first time taught medical deontology in Iasi, and who served during the 1913 war and between 1916 and 1919. He was awarded the Order of Commander of the French Legion of Honor; dr. **Mihai Manicatide** (1867-1953), founder of Iasi School of Pediatrics in "Sf. Spiridon" Hospital, participated in the First World War on the Moldavian front; dr **Constantin C. Dimitriu** (1894-1960), founder of the Iași School of Semiology and Gastroenterology took part in the First World War as a trainee and as an undergraduate in the Iaşi hospitals; Dr. **Alexandru Ionescu-Matiu** (1883-1975), an outstanding pharmacist, head of led the Central Chemistry Lab of the Romanian Army; **C. Ionescu-Mihăieşti**, specialized at the Pasteur Institute of Paris, fought during the war in the campaign against cholera, in 1913, in Bulgaria and then against exanthema, working in the Experimental Laboratory of Medicine evacuated to Iasi (1916) and Harkov (1917), mainly in making serums and vaccines needed by the allied armies in the fight against all sorts of epidemics. Some of the doctors who worked in this field were: **Prof. dr. Ion Cantacuzino**, prof. dr. Alexandru Slatineanu, dr. Mihai Ciucă, dr. Petru Condrea, dr. Stefan Nicolau (3).

Prof. dr. Ion Cantacuzino

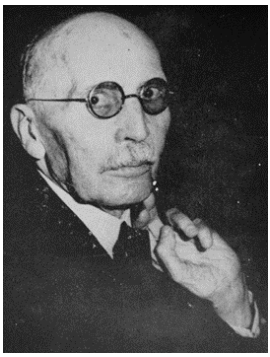
Alexandru Slătineanu (1873-1939) was decorated in 1914 with the Military Virtue for the organization of the Laboratory of Warfare Bacteriology. With his own means, private and public subsidies, he started a laboratory that could successfully face the needs of the country during the Great War. Moreover in 1917 he set up a

new method of preparation of anti-cholera vaccine that could be administered in a single dose at the Institute of Bacteriology in Harkov. In 1916, when Romania joined the Entante he was Head of the Second Army Sanitary Service and fought against cholera on the Dobrodgea front and among the war prisoners in Galaţi. In 1917, he joined, under Professor Cantacuzino`s command, the fight against exanthemas typhus. For his war contributions he was awarded the Order of Queen Maria (1st Class, 1917) Commander of the Spoon Crown and Knight of the French Legion of Legion (1918) (4).

Prof. dr. Alexandru Slătineanu

In 1918, Professor Slătineanu hosted the Experimental Medicine Laboratory of Professor Ioan Cantacuzino that had to be evacuated from Bucharest. In his modest laboratory in Iasi, 18 Muzelor St. the serums and vaccines were prepared not only for the Romanian, Russian and French armies operating on this front but also for the local civilian population and refugees who fled the foreign occupation, saving in this way import huge sums of money.

After the outbreak of the Great War a lot of other physicians served in the Romanian Army. **Mihai Ciucă** (1883-1969) fought against numerous epidemics, as Head of the Laboratory of the 1st Corps of Army and then as Head of the Military Hospital no.2 in Iasi. He had to fight against smallpox, tetanus, gangrene, recurrent fever, influenza and exanthemas typhus.



Prof. dr. Mihai Ciucă

Petru Condrea (1888-1967), professor of bacteriology, took part in the First World War as a prosecutor of all hospitals and head of the screening departments of the contagious hospitals in Piatra Neamt (1916-1918). In 1918-1919 he worked on the production of serums and vaccines in Professor Slatineanu's first laboratory of bacteriology, where he hosted the experimental medicine laboratory of Professor Ioan Cantacuzino evacuated from Bucharest.

Gheorghe Năstase (1887-1975), an intern, the future professor of dermatology, was, in the summer of 1913 sergeant who was responsible cholera cases in the campaign in Bulgaria. He began his medical activity on the front, treating the wounded. He was mobilized until March 1st, 1918 (3).

Stefan Nicolau (1896-1967), future professor of microbiology, as a young graduate, participated in the First World War on the Moldavian front (4).

Vasile Răşcanu (1885-1978) was mobilized when he graduated from the Faculty of Medicine and sent to the front in the campaign in the Balkans. He participated in the vast anti-cholera campaign initiated and

led by professors Ion Cantacuzino, Alexandru Slatineanu and Mihai Ciucă. With Romania's entry into the Great War in 1916, he was again mobilized and sent to the front, being directly involved in the fight against the exanthematical typhus epidemic that broke out in the winter of 1916 and then in 1917.

Other doctors, members of the Society of Physicians and Naturalists of Iasi died on the front: **Alexandru Brumă, Iacob Ţăranu. Mircea Gane, Victor Imervol, August Muler** (5)**.**

About 350 doctors and over 2,000 health workers in Romania gave their lives to the great task of unifying Romania in the First World War.

During the war, the scientific activity of the Physicians and Naturalists Society was interrupted, and the journal ceased to be published for about 5 years. The headquarters of the Society were used by the Faculty of Medicine for courses, its premises were rebuilt as a hospital and then bombarded.

It was not until 1920 that the scientific medical movement began to return to normal life by bringing together the members of the Society of Physicians and Naturalists and by planning scientific meetings and presentations of clinical and laboratory cases. The volume that bought together the scientific activity in 1920-1921 meant a step forward in the scientific and cultural life Iasi. This issue gave scientists the chance to gather together the energies of Iasi scientists that for several years were hindered to publish. Their energies were put instead to the service of the country.

The foreword was an appeal to medical colleagues asked to contribute with all their love of science to attend the meetings of the Society and to come with contributions able to maintain the regular publication of the journal by means of lectures and presentations. At the same time, it is stressed the fact that the newsletter published in Romanian was a means of meeting the needs of the Bessarabian students who were not proficient in French the language, in which the Bulletin was published.

The foreword also asked colleagues to pay tribute to all physicians who sacrificed their lives in the fight for the Great Union of Romania (6).

MOLECULAR AND CELL BIOLOGY TRANSLATIONAL RESEARCHES IN THE MANAGEMENT OF ORAL PREMALIGNANT LESIONS

Traditionally, according to international standards, research in general and implicitly medical research is divided into two categories: basic and applied. Basic medical research is focused on better or fuller understanding of both normal cellular and molecular mechanisms as well as those of different diseases, the findings not being always developed into useful clinical applications. Applied research is directed towards a specific aim and/or solving a problem, such as new therapies and/or diagnostic methods, etc. (1, 2).

In this respect, the purpose of translational research is to connect basic research to patient care (from laboratory to bedside), to integrate molecular and cell biology research with clinical research, facilitating the development of laboratory findings into clinical applications. Thus, clinical observations on the occurrence and progression of some diseases and/or efficacy of various therapies should be the starting point of basic research aimed to provide clinicians with answers, biomarkers as specific and useful as possible for prognosis and/or early diagnosis, select targeted therapies and assess the efficacy of therapy. This constant feedback may lead to improved management of some diseases with major population impact (2, 3).

A good example of translational research in the field of human pathology is represented by the studies on malignant transformation in different locations. In the oral mucosa, they pointed out that the development of oral squamous cell cancer is a two-step process indicating the initial presence of a precursor, a premalignant lesion (3, 4).

According to statistical studies, oral cancer is the most common neoplasm and is a major public health problem, in developing countries being the leading cause of death. It accounts for 2-4% of the malignancies in the Western countries and 40% of all cancers in India. A key factor in the increasing prevalence of these tumors is related to their diagnosis and treatment only in advanced stages (3-5).

Clinical diagnosis is often difficult because subjective and objective manifestations are nonspecific and do not correctly reflect the degree of damage to epithelial and connective tissues. Moreover, unfortunately patients present to the dermatologist and/or dentist when the disease is in a late-stage, transformed (6,7).

In over 50% of cases, this type of carcinoma develops on premalignant lesions, of which the most common are leukoplakia, actinic cheilitis, oral lichen planus, and oral submucous fibrosis (8).

Malignant transformation rate of these lesions is approximately 17% with a mean period of 7 years after diagnosis. The highest transformation rate is seen in heterogeneous erythroplakia and erythroleukoplakia with dysplastic changes (4). However, some studies show that 16% to 62% of oral leukoplakic lesions show characteristic changes of squamous cell carcinoma at the time of diagnosis (3, 9, 10).

Despite advances in surgical, radiological and chemotherapeutic treatment, the 5-year survival rate for oral cancer has not improved significantly in recent decades

still being around 50-55% (11-13).

Given the constant exposure to various internal and external environmental factors, oral mucosa is frequently under inflammatory stress, explaining its vulnerability to infectious/inflammatory processes such as those involved in carcinogenesis (14).

The results of numerous translational researches of molecular and cell biology support the idea that epithelial-mesenchymal transition (EMT), an important event in epithelial cell malignant transformation, may be induced by a series of proinflammatory cytokines (15).

The identification by translational studies of the molecular changes during the early stages of premalignant oral lesion development before they become clinically manifest is an important step in understanding how cellular response is regulated during carcinogenesis at this level and for identifying biomarkers useful for the early diagnosis of these lesions (16).

In this respect, a series of studies aimed at identifying the involvement of such molecules as tumor necrosis factor (TNFα), interleukin-6 (IL-6), metalloproteinase-2 (MMP-2) and cyclooxygenase-2 (Cox-2) in creating a micro medium suitable for malignant transformation at oral mucosa level (17,18).

It has been found that evaluating the role of IL-6 and TNFα cytokines in the early stages of oral carcinogenesis, before carcinoma becomes invasive, requires identifying and establishing correlations between their expression and/or activation/inhibition of some signaling pathways (18).

Thus, TNFα influences both angiogenesis by IL-6 and vascular endothelial growth factor (VEGF) stimulation and tissue remodeling by metalloproteinase stimulation (19-20). Increased TNFα expression in oral premalignant lesions influences IL-6 and MMP-2 levels, thus revealing the intricate roles of these molecules in what may be called the molecular mosaic specific to oral premalignant lesions (20).

IL-6 is considered a marker of malignancy, with sensitivity of 60-70% and specificity of 58-90%. However, studies on the diagnostic and prognostic value of this molecule are scarce and fairly controversial (17-20). In oral squamous cell carcinomas, it is believed to act as immunosuppressive molecule that facilitates the "eludation" of the immune system control mechanisms, the increased serum IL-6 levels being negatively correlated with prognosis (18).

Also, some studies indicate that on one hand this cytokine is stimulated early in oral premalignant lesions, prior to their transformation into carcinoma, and, on the other hand, its expression is much increased in premalignant compared to malignant lesions (19 -21).

As to Cox-2, researches revealed increased expression in both oral premalignant lesions and malignant tumors, depending on the intrinsic morphological characteristics and with prognostic relevance (20-23).

However, the association of COX-2 overexpression with poor prognosis remains controversial, although it is known that increased levels of prostaglandin E2 (PGE2), metabolite product of Cox-2 catalytic action, are associated with an increased risk of invasiveness and angiogenesis in the early stages of carcinogenesis (19,20).

Several cell and molecular biology studies indicate that cell interactions specific to these premalignant lesions are influenced by the expression of matrix metalloproteinases (MMPs). These are expressed by both tumor cells and stromal macrophages and endothelial cells. Some authors also suggest that patients in which increased MMP expression in stromal cells is detected have a poor prognosis because of its association with the

risk of lymphatic metastasis (1, 16, 20).

The results of the published studies, some of which were conducted in the Department of Cell and Molecular Biology of the Iasi "Grigore T. Popa" University of Medicine and Pharmacy revealed that in all leukoplakic lesions the increase in TNFα and IL-6 levels are associated with elevated Cox-2 and MMP-2 levels. Lesions with a mild degree of dysplasia exhibit decreased expression of TNFα, IL-6 and Cox-2 and increased expression of MMP-2 compared to lesions with a higher degree of dysplasia. Thus, Cox-2 expression is directly proportionally stimulated by proinflammatory cytokines TNFα and IL-6 and is associated with the severity of dysplasia. In contrast to these results, it was found that MMP-2 expression is inversely correlated with both TNFα, IL-6 and Cox-2 levels and the degree of dysplasia. IL-6 positively affects Cox-2 expression and negatively TNFα and MMP2 expression. The same correlations have been identified in other premalignant lesions, such as erosive oral lichen planus and erosive actinic cheilitis.

In clinical practice, despite the numerous data documenting its efficacy chemoprevention is still in its infancy. New therapeutic strategies targeting several molecules whose functional intrication has been proven by the cell and molecular biology researches briefly reviewed above are needed so that this type of lesions to be diagnosed early and treated effectively (23).

Imiquimod, a topical preparation commonly used in the treatment of oral premalignant lesions, may stimulate the production of proinflammatory cytokines like TNFα and IL-6, thus explaining such side effects as oral aphthous ulcer. Hence the need of combining imiquimod with other treatments such as corticoids with inhibitory effect on TNFα expression (22).

As shown above, Cox-2, overexpressed in various types of premalignant lesions may be a molecular target in their prevention and therapy. Clinical studies have shown that treatment with selective Cox-2 inhibitors reduces the formation of intestinal, esophageal, tongue, breast, skin, lung and bladder tumors (20-22).

Selective Cox-2 inhibition is also a method proposed for chemoprevention of malignant transformation of premalignant lesions. Cox-2 inhibitors have important advantages because they are active on the oral mucosa and have few contraindications (15, 19).

The current therapeutic management of oral premalignant lesions and oral squamous cell carcinoma is based on clinical data, often nonspecific, and some anatomopathological parameters insufficient to differentiate between severe and mild or moderate lesions. Therefore, the use of therapeutic, chemical and physical agents is often accompanied by numerous adverse effects, their incompletely elucidated explanation can be improved by the correlated study of the involved molecules. Under these conditions, it is once again revealed the importance of identifying through molecular and cell biology translational research of the specific molecular markers necessary for identifying and developing targeted and personalized therapeutic strategies.

SINDROMUL HEPATO-PULMONAR (SHP)

Laura Bozomitu[1], Evelina Moraru[2], B. Stana[2], M. Burlea[1], G. Aprodu[3], D. Moraru[1]
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină
1. Clinica a V-a Pediatrie
2. Clinica a II-a Pediatrie
3. Clinica de Chirurgie Pediatrică
Spitalul Clinic de Urgenţe pentru Copii "Sf. Maria" Iaşi

HEPATO-PULMONARY SYNDROME (Abstract): The hepato-pulmonary syndrome (HPS) is a rare complication of liver cirrhosis, with poor outcome; the term includes liver disease, increased alveolo-arterial gradient and intrapulmonary vascular dilations, described by Fluckiger, Kennedy and Knudson. HPS impairs survival in cirrhotic patients and the posttransplant outcome is altered in correlation with severity of HPS. Combined determination of SaO_2 in clino- and orthostatic position by a pulsoximeter is a simple test for HPS identification in patients with chronic liver disease or non-cirrhotic portal hypertension. **Key words**: HEPATO--PULMONARY SYNDROME, LIVER CIRRHOSIS, PORTAL HYPERTENSION

SHP este o complicaţie rară, cu prognostic rezervat în ciroză. În 1884, Fluckiger a descris pentru prima dată o femeie cu ciroză hepatică, cianoză şi hipocratism digital. Termenul de SHP (triada = boală hepatică, gradient alveolo-arterial crescut şi evidenţierea dilataţiilor vasculare intrapulmonare) a fost reluat în 1977 de către Kennedy şi Knudson (1). Aceste anomalii vasculare predomină în câmpurile pulmonare inferioare. Deoarece gravitaţia induce creşterea fluxului sanguin spre câmpurile pulmonare inferioare, hipoxemia se accentuează când se trece de la poziţia clinostatică la ortostatism.

Date privind incidenţa SHP sunt limitate şi estimările prevalenţei variază pe măsură ce sunt folosite definiţii diferite pentru SHP (1,3%). Rydell şi Hoffbauer (1956) au descris un băiat de 17 ani cu ciroză, vase pulmonare dilatate şi fistule arteriovenoase la autopsie (3). Hales descrie şi el câţiva pacienţi de vârstă mică având aceleaşi caracteristici, deci SHP poate apare şi la copil. Bolile hepatice acute şi cronice au fost asociate cu SHP (4,5,6). Cel mai frecvent, SHP apare în bolile cu progresie spre ciroză în special criptogenică, alcoolică, ciroza biliară primitivă şi HVB sau HVC. Totuşi, apariţia SHP la cei cu hipertensiune portală (HTP) noncirotică sugerează că ciroza nu este condiţia esenţială pentru dezvoltarea SHP. În unele studii există sau nu o corelare între SHP şi testele hepatice (bilirubina, timp Quick, albumina). De asemenea, alte studii găsesc asocierea SHP cu spider nevi şi alte manifestări cutanate. Hipoxemia uşoară apare la aproximativ 1/3 din toţi pacienţii cu boală cronică hepatică şi este multifactorială, din cauză că alte anomalii cardiopulmonare (efuzie pleurală, ascită) sunt frecvente la aceşti pacienţi şi pot coexista cu SHP. Principalele caracteristici ale SHP sunt platipnea (dispnee indusă de ortostatism şi ameliorată de clinostatism) şi ortodeoxia (deoxigenare arterială indusă de ortostatism şi ameliorată de clinostatism). Deşi aceste fenomene sunt patognomonice pentru SHP, ele sugerează net acest diagnostic în contextul disfuncţiei hepatice.

Simptomele respiratorii sunt tot mai frecvente la pacienţii cu boli cronice hepatice astfel încât 50-70% dintre aceştia acuză „scurtarea respiraţiei" (1). Diagnosticul diferenţial al dispneei este extensiv la aceşti pacienţi, fiind necesară enumerarea unor cauze numeroase. În ultimii 15 ani anomaliile vasculare pulmonare au devenit recunoscute ca entităţi clinice importante care influenţează supravieţuirea şi candidatura la transplant hepatic.

Cea mai comună anomalie, SHP, apare când vasodilataţia pulmonară alterează oxigenarea arterială. Acest sindrom este actualmente recunoscut la mai mult de 15-20% din pacienţii aflaţi în curs de evaluare pentru OLT (transplant hepatic ortotopic).

Prezenţa SHP creşte mortalitatea cirozei şi poate influenţa frecvenţa şi severitatea complicaţiilor HTP (3).

DEFINIŢIE

SHP se defineşte clasic printr-un gradient crescut alveolo-arterial al oxigenului ($AaPO_2$) în aerul din cameră (>15 mmHg sau >20 mmHg la pacienţii cu vârsta mai mare de 64 ani) cu sau fără hipoxemie care rezultă din vasodilataţia intrapulmonară în prezenţa disfuncţiei hepatice sau a HTP. Din punct de vedere practic identificarea pacienţilor cu $PaO_2 < 70$ mm Hg este utilă pentru recunoaşterea celor cu SHP clinic semnificativ. Studii recente subliniază că este necesară excluderea tuturor celorlalte cauze de disfuncţie cardiopulmonară pentru a stabili diagnosticul SHP. Totuşi, este tot mai evident că SHP poate coexista cu alte anomalii cardiopulmonare şi contribuie semnificativ la anomaliile schimburilor gazoase.

În plus, $AaPO_2$ creşte în mod normal cu vârsta şi variază semnificativ, chiar la adulţii sănătoşi. Deci utilizarea valorilor peste intervalul de confidenţă de 95% pentru $AaPO_2$ corectat în funcţie de vârstă este importantă pentru a evita supra-diagnosticarea SHP(1).

FIZIOPATOLOGIE

1. Mecanisme la om

O problemă fundamentală în patogenia SHP este faptul dacă mecanismele alterărilor vasculare pulmonare sunt similare cu cele implicate în alterările sistemică şi splanhnică din statusul circulator hiperdinamic din ciroză.

SHP apare mai frecvent în ciroza de diferite etiologii . Totuşi există controverse dacă prezenţa sau severitatea vasodilataţiei intrapulmonare şi a SHP se corelează cu severitatea bolii hepatice subjacente iar studiile au găsit SHP în ambele cazuri-ciroză compensată sau în stadiul final. Recent SHP a mai fost recunoscut la pacienţii cu HTP în absenţa cirozei (tromboza venei porte, hiperplazia regenerativă nodulară, fibroza hepatică congenitală şi sindromul Budd-Chiari) şi a fost raportat în hepatitele acute şi cronice în absenţa HTP. Acestea arată că SHP se dezvoltă şi în absenţa bolii hepatice avansate iar evenimentele fiziopatologice care survin în microvasculatura pulmonară a pacienţilor cu SHP sunt relative faţă de circulaţiile sistemică şi splanhnică.

Markerul patogenic al SHP este dilataţia microvasculară în cadrul circulaţiei arteriale pulmonare. Aceste modificări pot rezulta din scăderea tonusului arteriolar pre-capilar (izolat) sau se pot datora unor mecanisme adiţionale (angiogeneză, remodelare, vasculogeneză) sugerate mai recent (3). În SHP la om vasodilataţia rezultă din producţia excesivă vasculară de vasodilatatori, în special oxidul nitric (NO). Acest lucru se bazează pe observaţia că nivelele de NO expirat, care măsoară producţia pulmonară de NO, sunt crescute la pacienţii cirotici cu SHP şi se normalizează după OLT, odată ce SHP se remite. În plus, la un caz raportat în literatură s-a arătat că inhibarea acută a producţiei de NO sau administrarea N^G-nitro--L-arginin-metil esterului (L-NAME) sau a albastrului de metilen inhibitor de GMP ciclic ameliorează tranzitoriu SHP (1,3,4).

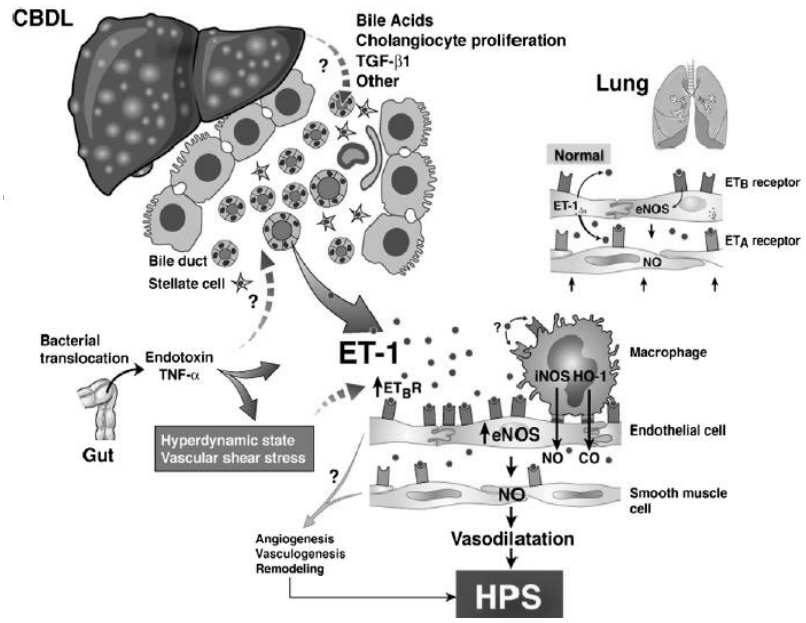

Fig. 1. Mecanisme şi tratamente posibile în SHP experimental, după Palma DT, Fallon M

Totuşi, un studiu recent a arătat că administrarea L-NAME inhalator nu a ameliorat net vasodilataţia pulmonară, suspicionând faptul că alţi factori decât efectele NO derivat din NOS asupra tonusului vascular contribuie la SHP.

Mecanismele exacte ale hiperproducţiei endogene de NO şi relaţia cu prezenţa HTP, cu circulatia hiperdinamică şi gradul leziunii hepatice, rămân necunoscute. În plus, nu s-a stabilit încă dacă alţi mediatori, cum ar fi monoxidul de carbon derivat din hemoxigenază,(3), ar putea contribui la vasodilataţia intrapulmonară şi ar explica lipsa ameliorării SHP odată cu inhalarea NO la unii pacienţi.

2. Mecanismele SHP experimental

CBDL (ligatura cronică a canalului biliar comun) la şoareci este singurul model experimental ce reproduce caracteristicile fiziologice ale SHP la om (fig.1). Este unic printre modelele de rozătoare cu ciroză şi/sau HTP prin faptul că alte modele folosite frecvent cum ar fi ciroza prin thioacetamidă şi ligatura parţială a VB (vezica biliară) nu duc la dezvoltarea SHP. Studii recente la animalele cu CBDL s-au concentrat pe rolul vasoconstrictor al eicosanoizilor şi asupra creşterii celulelor macrofage-like intravasculare (1, 3). Studii subsecvente au identificat creşterea sintetazei endoteliale vasculare pulmonare a NO (eNOS) ca sursă majoră de producţie pulmonară de NO (6) şi au demonstrat că administrarea de L-NAME a ameliorat hipoxemia după CBDL (7). Studiile ulterioare au arătat că o creştere a producţiei hepatice de endotelină 1 (ET-1) cu eliberarea ei în circulaţie este un mecanism trigger al creşterii eNOS pulmonare şi al debutului vasodilataţiei după CBDL. Acest efect poate fi mediat de o creştere a expunerii receptorului endotelinei B (ETB) endoteliale vasculare pulmonare, indusă de stress, care duce la creşterea producţiei de NO endotelial prin ET-1. Conform acestui fapt, administrarea unui antagonist selectiv al RETB la animalele CBDL va scade eNOS endotelială pulmonară şi nivelele RETB cu ameliorarea semnificativă a SHP.

Date recente susţin faptul că epiteliul biliar este o sursă importantă de ET-1 hepatică după CBDL şi pot explica susceptibilitatea unică a anomaliilor CBDL la SHP. Odată cu progresia SHP experimentale există o acumulare de macrofage vasculare. Aceste celule produc tranzitor sintetaza inductibilă de NO (INOS) (6,7) şi progresiv hemoxigenaza 1 (HO-1). Aceste evenimente contribuie la vasodilataţia suplimentară prin producerea de NO din INOS şi CO derivat din HO-1. Astfel, inhibarea HO ameliorează SHP experimental. În plus, tratamentul prelungit al animalelor CBDL (început din momentul ligaturării) cu Norfloxacină pentru a inhiba translocaţia bacteriană şi producţia de TNF-alfa va scade acumularea macrofagelor şi va preveni creşterea tranzitorie a INOS, susţinând faptul că TNF-alfa contribuie la acumularea macrofagelor. Mai mult, pentoxifilina, inhibitor fosfodiesterazic nonspecific care creşte nivelele AMPc intracelular şi inhibă TNF-alfa produs în macrofage (8), poate preveni debutul sau poate scade severitatea SHP. Ambii agenţi administraţi la debutul leziunii hepatice influenţează dezvoltarea statusului hiperdinamic şi pot modifica expresia R-ETB şi evenimentele de semnalizare legate de ET în microvascularizaţia pulmonară. Alte date noi despre modelul CBDL arată că o secvenţă de evenimente legate în parte de creşterea stresului vascular şi de producţia hepatică de ET-1 poate declanşa debutul SHP experimental. Observaţia că nivelele hepatice şi plasmatice ale ET-1 cresc în prima săptămână după CBDL) sugerează că producţia şi eliberarea ET-1 hepatice apare la un nivel modest al proliferarii ductelor biliare. Descoperirea că macrofagele se acumulează în microvasele pulmonare şi că pot fi influenţate de inhibarea TNF-alfa susţine faptul că aceste celule pot de asemenea contribui la vasodilataţie. Figura ilustrată mai sus include posibile ţinte terapeutice pentru SHP conform datelor experimentale.

MANIFESTĂRI CLINICE

Caracteristicile clinice ale SHP constau tipic în acuze respiratorii şi manifestări asociate bolii hepatice cronice. Debutul insidios al dispneei, de tip expirator, este cea mai comună problemă, deşi nespecifică. Platypnea (platipnea) (scurtarea respiraţiei exacerbată de ortostatism şi ameliorată de clinostatism) şi orthodeoxia (hipoxemie exacerbată în ortostatism) sunt clasic descrise şi rezultă din creşterea gravitaţională a fluxului sanguin prin vasele dilatate de la bazele pulmonare (1). În timp ce orthodeoxia a fost observată în unele situaţii patologice, cum ar fi post-pneumectomie, tromboembolii pulmonare recurente şi defecte septale atriale (foramen ovale permeabil), este înalt specifică pentru SHP în condiţiile bolii hepatice (8). "Sensibilitatea" orthodeoxiei pentru SHP este relativ scăzută dar creşte sever în cazurile de SHP. Tusea este un simptom rar. Angioamele stelate sunt frecvent raportate în SHP dar apar mereu la ciroticii fără SHP. Un studiu a observat că pacienţii cu aceste leziuni cutanate aveau vasodilataţie pulmonară mai mare şi gradienţi de oxigen alveolo-arterial mai mari decât la cei fără angioame stelate ($AaPO_2$ de 20 mm Hg versus 8mm Hg). În sfârşit, clubbing fingers (degete hipocratice) şi cianoza distală, când apar în condiţiile de hepatopatie sau HTP, ar trebui să ridice suspiciunea de SHP (1).

DIAGNOSTIC

Caracteristicile diagnostice ale SHP includ boala hepatică sau HTP, gradient al oxigenului alveolo-arterial ($AaPO_2$) crescut, dovada vasodilataţiei intrapulmonare. În prezenţa unei boli cardiace sau pulmonare asociate, stabilirea diagnosticului SHP poate fi dificilă. Există un algoritm pentru diagnosticul SHP (fig. 2). O evaluare logică a dispneei la pacientul cu boală hepatică sau HTP începe cu un istoric atent şi o examinare fizică. Astfel, clinicianul poate face distincţia între

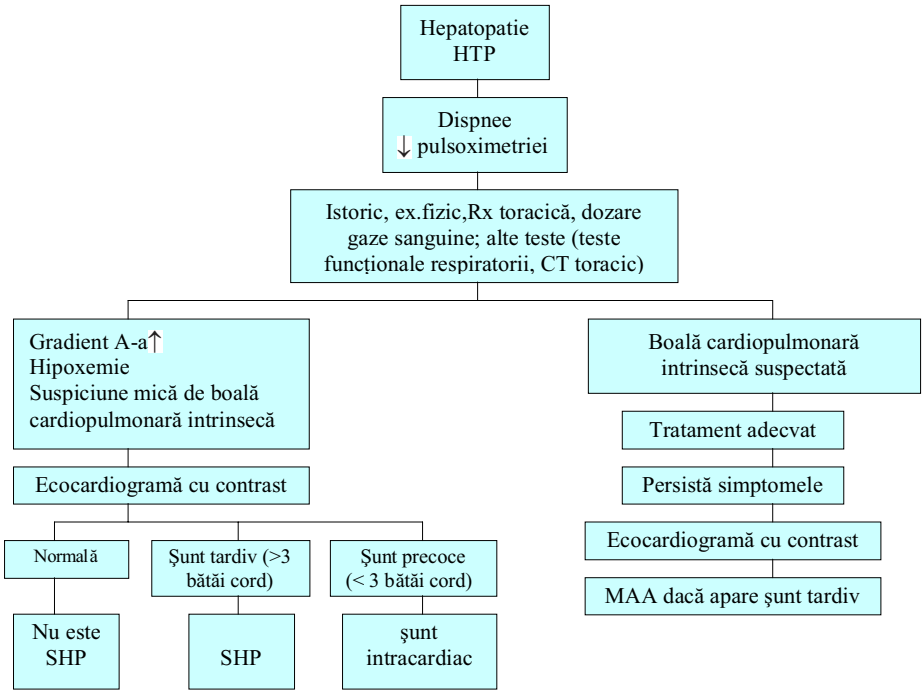

Fig. 2. Diagnosticul SHP, după Palma DT, Fallon M

BPOC, insuficienţa cardiacă cronică sau ischemie miocardică. Totuşi, dacă se pot exclude cauzele obişnuite de dispnee şi, în mod particular, dacă platipnea sau hipocratismul digital sunt prezente, evaluarea suplimentară pentru SHP este inerentă.

1. Evaluarea oxigenării arteriale

La pacienţii cu boală hepatică şi dispnee sau hipocratism, sau la cei propuşi pentru transplant, pulsoximetria este un test simplu, neinvaziv, de screening, pentru hipoxemie iar SaO_2 scăzută ar trebui să implice analiza gazelor sanguine arteriale (AGSA). Totuşi, interpretarea unei SpO_2 ca „normală" ar trebui făcută cu prudenţă, deoarece pulsoximetria poate supraestima SaO_2 la aproape 50% din pacienţii cu ciroză(1). Astfel, pentru a detecta hipoxemia, ar trebui considerată analiza gazelor arteriale (AGA), când valorile SpO_2 sunt mai mici sau egale cu 97%. În plus, dacă hipoxemia sau SHP sunt suspicionate pe baza istoricului şi a examenului fizic, AGA trebuie efectuată în timpul respirării aerului din cameră, în afara pulsoximetriei. În SHP, analiza gazelor relevă un gradient crescut alveolo-arterial ($AaPO_2$) cu sau fără hipoxemie. Limita superioară a $AaPO_2$ normală pentru aerul din cameră la o vârstă dată (interval de confidenţă $>95\%$) poate fi calculată prin ecuaţia: $AaPO_2 = ş0{,}26$ x vârsta-0,43ţ+10 (2). Dacă sunt decelate anomalii de schimb gazos sunt necesare radiografia şi testele funcţionale pulmonare pentru a evalua prezenţa altor anomalii pulmonare. Deoarece tulburările cardiopulmonare fără legatură cu hepatopatia sau cele legate de ascită sunt mai frecvente decât SHP, tratarea acestora înainte de evaluarea suplimentară pentru SHP este mai rezonabilă, în absenţa unei hipoxemii semnificative ($PaO_2 < 70$ mm Hg). ERS Task Force a propus un sistem de clasificare care utilizează presiunea arterială a oxigenului (PaO_2) pentru a stadializa severitatea SHP. Conform acestui sistem, o $PaO_2 < 50$ mm

Hg indică SHP foarte sever, $PaO_2 = 50$ şi < 60 mm Hg sugerează SHP sever iar $PaO_2 = 60$ şi < 80 mm Hg corespunde unui SHP moderat. Stadializarea severităţii SHP este importantă în predicţia supravieţuirii (3) şi determinarea momentului şi riscurilor pentru OLT (3,6,8).

2. Ecocardiografia cu contrast

Dacă se suspicionează SHP, ecocardiografia cu contrast transtoracică cu microbule este testul screening preferat pentru vasodilataţia intrapulmonară (1). Aceasta se realizează prin injectarea intravenoasă de ser fiziologic agitat în timpul ecocardiografiei transtoracice normale, producând microbule vizualizate sonografic. Acest bolus opacifiază ventriculul drept (VD) în câteva secunde iar în absenţa şuntului dreapta-stânga, bulele sunt absorbite de plămâni. Dacă este prezent un şunt intracardiac, agentul de contrast intră în VS în timpul a 3 bătăi cardiace (sunt precoce). Dacă şuntul intrapulmonar caracteristic SHP este prezent, VS se opacifiază la cel puţin 3 bătăi de cord după VD (şunt tardiv). În timp ce mai mult de 40% din cirotici au ecografia de contrast pozitivă (3), numai un subgrup din aceşti pacienţi au o suficientă vasodilataţie pentru a determina un schimb gazos anormal şi îndeplineşte criteriile pentru SHP. Dacă un pacient cu boală hepatică sau HTP şi hipoxemie are o ecocardiogramă de contrast pozitivă, în absenţa unei boli semnificative cardiopulmonare, diagnosticul de SHP este stabilit.

A apărut un sistem de scor semnificativ pentru evaluarea şuntului intrapulmonar în timpul ecocardiografiei de contrast, deşi rămâne neclar dacă gradul şuntării se corelează cu gradul anomaliilor de schimb gazos.

3. MAA scan (macroaggregated albumin scan)

La pacienţii cu hipoxemie care prezintă vasodilataţie intrapulmonară şi boală cardiopulmonară intrinsecă, MAA scan (scintigrafie cu macroagregate de albumină marcate cu technetium) poate fi utilă în definirea contribuţiei SHP la anomaliile de schimb gazos. În această investigaţie, agregate de albumină radiomarcate, cu diametrul de aproximativ 20 μm sunt injectate în sistemul venos. În mod obişnuit, particulele de această mărime sunt captate în microvasculatura pulmonară iar scintigrafia relevă o captare aproape normală în plămâni. În prezenţa unei şuntări intrapulmonare semnificative, o fracţie din microagregatele de albumină trece prin plămâni spre circulaţia sistemică. Scintigrafia mai indică o captare în alte organe, permiţând calcularea fracţiei de şunt. Într-un studiu, MAA scan a fost pozitivă doar la pacienţii cu SHP şi $PaO_2 < 60$ mm Hg şi nu la cei cu BPOC şi cu grad similar de hipoxemie(3). Totuşi, MAA scan este mai puţin sensibilă decât ecocardiograma de contrast şi poate fi cea mai utilă în a vedea dacă SHP contribuie la hipoxemie la pacienţii cu boală pulmonară obstructivă concomitentă.

4. Explorări funcţionale pulmonare

În timp ce testele funcţionale pulmonare anormale sunt frecvent observate în SHP, acestea nu au o specificitate mare. În absenţa unei boli concomitente obstructive sau restrictive pulmonare, valorile capacităţii pulmonare totale şi ale ratei de flux expirator de la pacienţii cu SHP sunt în general normale. Afectarea difuziei este frecventă în SHP. Într-un studiu, capacitatea de difuziune a monoxidului de carbon (DLCO) era cu 80% mai mică decât valoarea predictivă la 15 din 18 pacienţi cu SHP (9). Totuşi, prezenţa DLCO scăzută cu spirometrie normală nu este specifică pentru SHP şi este observată de rutină la pacienţii cu boală pulmonară interstiţială precoce, boală vaso-ocluzivă şi anemie severă.

ALTE TEHNICI DE DIAGNOSTIC

Angiografia pulmonară este scumpă şi

Fig. 3. I.S., 9 ani, ciroza hepatica de etiologie neprecizata complicată cu sindrom hepato-pulmonar (colecţia Clinicii a II-a Pediatrie Iaşi – Prof. Dr. Evelina Moraru)

invazivă şi are o sensibilitate mică în decelarea vasodilataţiei intrapulmonare, deci nu este folosită de rutină în diagnosticul SHP.

CT de înaltă rezoluţie a toracelui şi evaluarea timpului de tranzit sanguin pulmonar sunt modalităţi diagnostice mai noi de evaluare a SHP. Într-un studiu recent gradul dilatării microvasculaturii pulmonare observată pe CT toracic se corela cu severitatea anomaliilor de schimb gazos într-o cohortă mică de pacienţi cu SHP, sugerând că este posibilă cuantificarea vasodilataţiei intrapulmonare. Într-un alt studiu, timpul de tranzit pulmonar al eritrocitelor, măsurat prin analiza ecocardiografică a complexelor serice umane albumină-aer-microbule din inimă, de asemenea s-a corelat cu anomaliile de schimb gazos, într-un grup mic de pacienţi cu SHP. Rămâne de văzut dacă aceste tehnici vor fi utile pentru diagnosticul SHP.

ISTORIE NATURALĂ ŞI PROGNOSTIC

Istoria naturală a SHP nu este complet elucidată. Cei mai mulţi pacienţi par să dezvolte vasodilataţie intrapulmonară progresivă şi schimburi gazoase deteriorate în timp (9), iar ameliorarea spontană este rară. Un studiu prospectiv recent a evaluat istoria naturală a SHP pe o cohortă de 111 pacienţi cu ciroză, din care 27 (24%) aveau SHP. Supravieţuirea medie a pacienţilor cu SHP a fost semnificativ mai mică (10,6 luni) faţă de cei fără SHP (40,8 luni). Mortalitatea a rămas mai mare la cei cu SHP după aprecierea severităţii bolii de bază a ficatului şi după excluderea pacienţilor ce fuseseră transplantaţi hepatic în timpul urmăririi. Cauzele morţii la pacienţii cu SHP au fost datorate în special complicaţiilor prin disfuncţie hepatocelulară şi cele ale HTP şi s-au corelat cu severitatea hipoxemiei în SHP.

Aceste date sugerează posibilitatea ca prezenţa SHP să fie un factor important care influenţează progresia bolii hepatice şi riscul complicaţiilor legate de HTP. În sfârşit, chiar şi o hipoxemie modestă legată de SHP se poate agrava în somn, pe baza observaţiilor cum că saturaţia nocturnă a oxigenului scade la un grup mic de pacienţi cirotici fără SHP (10).

Mortalitatea după OLT pare de asemenea să fie mai mare la pacienţii cu SHP comparativ cu cei fără SHP. Utilitatea severităţii SHP ca predictor al evoluţiei după OLT a fost evaluată prospectiv pe o cohortă

de 24 pacienţi cu ciroză şi SHP (10). Autorii au arătat că mortalitatea după OLT a fost mult crescută în SHP sever, în parte datorită apariţiei unor complicaţii rare postoperatorii recunoscute la cei cu SHP. O presiune PaO_2 preoperatorie =50 mm Hg izolată sau combinată cu o fracţie de şunt a albuminei macroagregate = cu 20% sunt predictorii cei mai „solizi" ai mortalităţii postoperatorii.

SHP poate afecta supravieţuirea la pacienţii cu ciroză iar prognosticul posttransplant se alterează proporţional cu severitatea SHP. Determinarea combinată a SaO_2 în clino şi ortostatism utilizând un pulsoximetru este un test simplu de identificare a SHP la pacienţii cu boală cronică hepatică sau HTP noncirotică. În studiul prospectiv numai 4/316 (1,3%) aveau SHP. Şunturile pot fi cuantificate prin scintigramă pulmonară şi se corelează mai bine cu valorile SaO_2 decât ale PO_2. Această corelaţie poate permite o estimare a severităţii şunt-volumului fără efectuarea scintigrafiei. În practică, determinarea saturaţiei O_2 arterial cu pulsoximetrul poate fi utilizată ca test screening simplu şi ajută la identificarea mai multor pacienţi cu SHP în scopul studiului patogeniei şi al dezvoltării strategiilor terapeutice.

EDITORIAL

GENOME EDITING: ALI BABA'S TREASURE OR PANDORA'S BOX ?

At the beginning of this decade a series of discoveries in the field of bacterial genetics has enabled the development of molecular biology technologies capable of changing the genetic structure of higher organisms. Overall, these technologies are known as genome editing and are based on the use of different nucleases that use the natural mechanisms to correct DNA mutations. Thus, such technology allows the correction of DNA sequences by inserting or removing fragments of interest.

The attempts to change the genetic material of a living organism are not new, but the methods used since the '90s of last century were marked by many difficulties and failures.

The first system used was that of nucleases of the type ZFNs (zinc finger nucleases) which have two parts: a domain binding to the DNA ("zinc finger" type) and a nuclease derived from the restriction enzyme *FokI* (1). This system is able to recognize a DNA sequence of 9 to 18 base pairs, but its use has difficulties, like a limited number of target sequences, a high rate of off-target effects and an increased cytotoxicity. The only advantage is the small size that allows the incorporation of such system in viral vectors such adenoviruses (2).

A second system applied was the transcription activator-like effector nucleases (TALENs) identified in *Xanthomonas* species. It also consists of two components: a nuclease and a DNA binding system (3). The nuclease is an enzyme derived from restriction enzyme *FokI*. The binding to DNA is provided by a repeating unit of 33-35 amino acid sequence. Of these the amino acids residues from positions 12 and 13 are variable and represent elements which ensure the specific recognition of DNA sequences containing a thymine at the 5' end. Compared with ZFNs, TALENs is characterized by a much lower rate of off-target effects and a low level of cytotoxicity (4).

The last genome editing system discovered at the beginning of this decade, is the more efficient. It consists of combination of Clustered Regularly interspaced Short Palindromic Repeats (CRISPR) and CRISPR Associated (Cas) proteins. This system, originally identified in *Streptococcus pyogenes*, is a natural defense mechanism against infections with plasmids and viruses in arches and bacteria. Naturally, Cas9 nuclease guidance is provided by two sequences of RNA: CRISPR RNA (crRNA) and transactivating CRISPR RNA (tracrRNA) that are complementary to different viral sequences of approximately 20 nitrogenous base pairs. In genome editing the two pieces of RNA are combined into one single guide RNA sequence (sgRNA) much easier to synthesize and use (5). Cas9 target DNA sequences must have a protospacer-adjacent upstream motif (PAM) that contains the sequence NGG (N could be adenine, cytosine, thymine or guanine), at which level Cas9 allows an enzymatic cut that produces a double strand breaks (DSB). The main advantages of using this editing system are: the low price, adaptability to different target sequence, high-throughput and possibility of multiplex editing (6).

Genome editing mediated by Cas9 nuclease is carried out by DBS, followed either by a randomly insertion/deletion via error-prone non-homologous end-joining pathway, or a controlled insertion of a foreign

DNA sequence via homology-directed repair (HDR) pathway, which generate a precise gene knock-in (7). Modifying the Cas9 nuclease (by controlled mutagenesis) enabled an enzyme which preserves the DNA binding ability but does not induce DNA breaks - dCas9 (*Cas9 death*). In this way, different groups are attached to dCas9 and they can modify the transcription of certain genes, provide the labelling of certain DNA sequences (for example, fluorescent labelling of telomeres) or change the epigenetic control of some gene's domains (8).

Genome editing via HDR or DSB is characterized by unwanted events (generation of insertions and deletions (indels) at target and off-target sites) so attempt have been made to develop more accurate technologies. An example is base editing, a system formed by a chimeric protein that consists of a DNA targeting module and a catalytic domain capable of deaminating of cytidine or adenine base. In this way is changed a DNA base along with the manipulation of the DNA repair machinery to avoid faithful end repair of the modified base (9).

Genome editing has had an explosive development, with applications in all fields of human pathology, from oncology to assisted reproduction.

In oncology, it has been attempted to change all specific processes of oncogenesis (6). Thus, it has tried to inactivate oncogenes (10), to activate repressed tumor suppressor genes (11), to develop Chimeric antigen receptor (CAR) T cells targeted against certain tumors (12), to develop methods of identification of telomeres lengths (13), to repress the activity of cytokine receptors (14), to develop methods of screening the genes implied in metastasis (15), to remove binding sites of microRNAs in order to block neoangiogenesis (16), to develop methods for monitoring tumor heterogeneity (17), to inhibit apoptosis by viral gene (18), and to develop methods of screening of new metabolic regulator (19).

Another field where the genome editing can be applied is the modification of human stem cells, thereby producing a virtually infinite number of corrected pluripotent cells. For this were used embryonic cells, marrow stem cells and cancer cells. In principle, it can be used in two major directions: the introduction of a pathogenic mutation into a normal stem cells line or the correction of a pathogenic mutation into a stem cell line obtained from a patient with a particular monogenic disease. The gene mutations correction was tried for *CFTR* gene in cystic fibrosis (21) *HBB* gene in sickle cell anemia and beta-thalassemia (22, 23) *JAK3* gene in SCID (24) *RPGR* and *MERTK* genes in retinitis pigmentosa (25, 26) *DMD* gene in Duchenne muscular dystrophy (27), *PKD1* or *PKD2* genes the polycystic kidney disease of adults (28) .

The application of genome editing in degenerative pathologies of the central nervous system provides therapeutic opportunities for the treatment of diseases such as Alzheimer's disease, Parkinson's disease, Huntington's disease or autism spectrum, but practical application is still limited by our ability to introduce cells with corrected genes in nervous central system (29).

Genome editing was used to destroy HIV-1 in latently infected cells, but unfortunately the virus quickly developed resistance against genome editing at a single antiviral target site (30).

Currently, through genome editing it is possible to change the embryos bearing various pathogenic mutations. Thus, this method was applied to correct the mutation in *HBB* gene which determines the beta-thalassemia (31) or *MYBPC3* gene involved in the pathology of hypertrophic cardiomyopathy (32). However, such an approach raises numerous bioethical issues mainly

related to genomic editing errors such as incomplete editing, inaccurate editing (off- and on-target effects) possible interference with other genetic events (pleiotropy, penetrance or intervention of environmental factors or epigenetic mechanisms). On the other hand, bioethical dilemmas are correlated with a possible change of human genome in the direction of eugenics, such as improving the biological quality of certain individuals with an emphasis on social inequalities (33, 34).

Also, genome editing was used for improving various biotechnology, functional biology or gene therapy, allowing the modification of a single pair of nitrogenous bases, genomic and epigenomic modification, genome-wide screening, production of new protein variants, animal or vegetable researches with the aim to improve food quality, the development of animal models for human genetic pathology, improvement of xenotransplantation, production of performant antimicrobial or antiviral treatment or development of innovative therapies in medicine (9, 34).

All the above provide the premises of an extensive development of genome editing with multiple applications in biotechnology and medicine, but on the other hand generate concerns about the inappropriate use of these methods, because of the possibility to change the genome of certain embryos and modify the development potential of some people in the detriment of individuals with no genomic changes.

NONALCOHOLIC STEATOHEPATITIS: THE MAINSTAY OF CLINICAL HEPATOLOGY

Nonalcoholic fatty liver disease (NAFLD) is a major cause of chronic liver disease and has now become a global epidemic affecting 1 in 4 adults worldwide (1). NAFLD encompasses two distinct conditions with distinct histologic features and prognosis: 1) nonalcoholic fatty liver (NAFL), which includes steatosis only, and 2) nonalcoholic steatohepatitis (NASH) characterized by steatosis and inflammation with hepatocyte ballooning, with or without fibrosis, which can progress to liver fibrosis, cirrhosis, hepatocellular carcinoma (HCC) and liver transplantation (2).

The global prevalence of NAFLD is about 25% (1) and the prevalence of NASH among NAFLD patients ranges from 10% to 59% among patients that underwent liver biopsy (1), meaning that millions and millions of people worldwide are at risk of cirrhosis and its complications. However, the true prevalence of NASH is not yet known, due to the need for liver biopsy (LB) to set the diagnosis, but current data show that 1 in 3 patients with NAFLD have NASH (1), while the global prevalence of NASH in general population ranges between 3%-5% (3). Even more alarming, an increase in NASH prevalence will soon parallel the rising rates in obesity, type 2 diabetes mellitus (T2DM) and metabolic syndrome - all three being the most important risk factors for NASH (4,5). Thus, in a recent study using a Markov model for predicting NAFLD/NASH progression in the USA showed an exponential increase in burden of disease, estimating that 33.5% of adult populations will have NAFLD, among which 27% will present with NASH, and 29% of patients with NASH will have advanced fibrosis by 2030 (6). Projected NAFLD cases will increase to 21%, from 83.1 million (2015) to 100.9 million (2030), while prevalent NASH cases will increase by 63%, from 16.52 million (2015) to 27.00 million cases (2030) (6). A Markov model was also used to estimate NAFLD/NASH disease burden modelled from 2016 to 2030 in eight countries (USA, United Kingdom, Japan, China, Germany, France, Italy and Spain) including a quarter of the world's population and showed that the prevalence of both conditions is expected to constantly rise in parallel with the epidemics of obesity, diabetes, and the metabolic syndrome (7). The highest rate of NAFLD population (26.3% in 2016) was estimated for the USA and is expected to increase by 18.3% (28.4% prevalence) to 100.9 million cases by 2030, whereas the population with NASH was estimated to increase at 56%, rising from 17.32 million cases (2016) to 27.00 million cases (2030). In China, the overall NAFLD population was estimated to increase from 17.6% in 2016 (246.33 million cases) to 29.1% in 2030, with 314.58 million cases. Among the European countries, the estimated NAFLD population in 2016 ranged from 18.45 million cases in Germany to 10.53 million cases in Spain, and by 2030 will have increased to 20.95 million cases in Germany, and 12.65 million cases in Spain. By the year 2030, the highest prevalence of NAFLD population was estimated in Italy (29.5%) and the lowest in France (23.6%). As to the NASH population, the highest number of cases in 2016 was re-

ported in China (32.61 million cases) and projected to increase to 48% (48.26 million cases) by 2030, while in the USA, the number of NASH cases was estimated to reach a peak of 56% (from 17.32 million cases in 2016 to 27.00 million cases in 2030). Spain is projected to have the highest proportion (29.5%) of NASH cases (792.110) by 2030 (7).

There are several other studies, reviews, and meta-analyses reporting the prevalence of NAFLD/NASH in different countries worldwide. A very recent one showed that in the European Union, the prevalence of NAFLD was estimated to 20-30%, with 3% having NASH, Romania and Hungary being mentioned with the prevalence of 20% and 22%, respectively (8). In Asia, prevalence of NAFLD ranges from 15% to 40%, and NASH ranges from 2% to 3%, while in Australia, NAFLD/NASH has become the most common liver disease, affecting a third of population. In North America, the prevalence of NAFLD reaches 24%, less than in South America (32%), while the Middle East has 31.8% - exceeding that in the USA. In Africa, the prevalence of NAFLD/NASH was estimated to be 13.5%, but it should be underlined that there is a lack of studies on the epidemiology of this disease in this continent. An almost similar prevalence of NAFLD/NASH was reported by Younossi *et al.* in a meta-analytic study (1) and in a recent review (9).

Of note, NASH is found not only in adults, but also in children and adolescents and to a high degree, paralleling the growing epidemic of childhood obesity, with an estimated of 7 million children/adolescents affected in USA only (10). NASH at a young age can progress to cirrhosis and end-stage liver disease (ESLD); one study reported that adolescents with NASH have 16 times higher chances to develop ESLD by the age of 20 compared to American youth with similar age and gender (11).

As mentioned previously, NASH prevalence is higher in patients with T2DM, obesity, and metabolic syndrome than in general population, largely due to a matching growth in the prevalence of this group of diseases. A recent study reported that the number of obese adults increased from 108 million (1980) to 671 million in 2016 (5). A similar increase in diabetes prevalence in adults - from 108 million (1980) to 422 million in 2014 - has been reported by another study (12).

In Romania, the first published study, in 2008, assessing the prevalence of NAFLD using ultrasound examination in hospitalized patients without liver diseases, reported a rate of 20% (13), and was followed more recently by other three studies (14-16) and a review (17).

To summarize, the prevalence of NASH has seen a tremendous growth over the last decades, turning it into an epidemic alongside obesity, diabetes, and the metabolic syndrome. However, it should be underlined that because of liver biopsy (LB) requirements for diagnosis, there are no accurate data on the prevalence of NASH at a global level given variations in assessment and definitions(18).

LB is the "gold standard" for the diagnosis of NASH and is regarded as the only method to distinguish NASH from NAFL (19). Still, its invasive nature, high cost, inter-and-intra-observer variability of histopathological interpretation, sampling errors, and the risk of rare but potentially life-threatening complications (20), make it unsuitable for disease diagnosis and monitoring in clinical practice, unrealistic and even impossible to be performed in millions of patients. The above-mentioned drawbacks of LB have led to the development of several noninvasive methods for liver fibrosis evaluation ranging from serum markers assays to advanced imaging techniques, representing a major advancement in clinical

hepatology, while some of them are already included in clinical practice guidelines for NAFLD including NASH (21). Intensive debates have been carried out in the past two decades between pros and cons (22), including the case of hepatitis C, a field where LB had been an important component in patient care and clinicians were reluctant to the introduction of noninvasive methods as an alternative to biopsy. Nowadays, LB is not any longer performed in the evaluation of liver fibrosis for decision making in chronic HCV antiviral therapy, being replaced by noninvasive methods. No doubt, this will be the case in NASH evaluation.

The economic burden of NAFLD/ NASH is huge, as evaluated by different methodologies. Thus, in a steady-state prevalence model to quantify the expected increase in the economic burden of NAFLD/NASH in the USA and four European countries (United Kingdom, Germany, France, and Italy), projections showed that in USA over 64 million people have NAFLD/NASH at a medical cost of about $103 billion annually, while in the Europe – in the 4 mentioned countries - there will be 30 million people with this disease, and with an annual cost of about 35 billion euros (23).

Younnosi *et al.* constructed lifetime Markov models for all stages of NASH, and a separate model to identify the increased burden of advanced NASH (fibrosis stage >3) and found that, in the USA, there are 6.65 million adults with NASH, with an estimated $222.6 billion cost during their lifetime, while the population with advanced NASH will cost $95.4 billion (24).

The natural history of NASH is not yet entirely known. What is known is that NASH is a main cause of chronic liver disease affecting millions of people worldwide. NASH is associated with an increased mortality, as it is the most important cause of death due to cardiovascular disease followed by malignancy, and liver-related disease (25). There is a higher incidence of HCC in patients with NASH than in general population (26) and NASH is the leading cause of HCC-related liver transplantation (2).

NASH was first described as a distinct entity by Ludwig *et al.* in 1980 (27) and remained for several years an obscure liver disease neglected by physicians, until two decades ago when it started to be the focus of attention, becoming nowadays a hot research topic and of great concern for the hepatologists, due to its high prevalence worldwide and its role in the development of liver cirrhosis and HCC.

Until five years ago, viral hepatitis (B and C) had been the focus of clinical research in hepatology. The advent of therapies that suppress hepatitis B replications and the highly effective direct acting antivirals curing HCV-infections in almost all patients, giving hope to see these infections eliminated by 2030 (28), switched the focus towards NAFLD and to one of its types, NASH - in particular, which has virtually replaced viral hepatitis and changed the perspective in hepatology.

VIRAL HEPATITIS-WHERE TO ? (Abstract) : Viral hepatitis is a serious health problem all over the world. The aim of the study is to present the actual achievements in the therapeutically field and the general knowledge concerning the subject. Are presented the etiological agents of the acute and chronic hepatitis with the focus on hepatitis B and C, which has become a priority of WHO, with an incidence of the diseases of 360 billion/year for hepatitis B and an sub estimated level for C hepatitis. The most used drugs are presented and the therapeutical combination meant to decrease biological and virusological markers (ALAT, viral load) and to ameliorate the histological aspects of the liver. In conclusion, acute and chronic viral hepatitis represents a challenge for epidemiologists who try to stop the spread of the disease, but also for the infectious diseases specialists and gastroenterologists. **Key words** : VIRAL HEPATITIS, ALAT, VIRAL LOAD, DRUGS.

INTESTINAL MICROBIOTA AND INFLAMMATORY BOWEL DISEASES

Introduction. Inflammatory bowel disease (IBD) includes two distinct disorders, hemorrhagic colitis also known as **ulcerative colitis** (UC) and **Crohn's disease** (CD). These are chronic inflammatory diseases of the digestive tract characterized by alternating periods of exacerbation and remission. In UC the lesions caused by inflammation are continuous, without areas of normal mucosa, affecting the rectum and extending proximally to the colon, but do not involve the ileocecal valve. Histologically, the inflammation is restricted to the mucous and submucous membrane, described as inflammatory infiltrate in lamina propria and crypt abscesses. Unlike UC, CD can affect any segment of the digestive tract, from the oral cavity to the anus, the lesions being discontinuous, asymmetric, and transmural. Histologically, granulomas are pathognomonic findings. The most common location of lesions is in the terminal ileum ("terminal ileitis").

Epidemiology. The incidence of IBD (6-20/100,000 population for UC and 5-6/100,000 population for CD) has increase in the recent years, with geographical variability in the US, England, Scandinavian countries, where this increase is alarming, compared to Central and South Eastern Europe (including Romania), Latin America, Asia, Africa where the incidence is much lower. It is estimated that over 2.2 million individuals have IBD in Europe, and it was found that industrialization and adoption of the Western lifestyle led to a higher increase in the frequency of CD compared to UC (1). In Romania, the incidence of IBD is 6.5/100,000 population, with slight south-west epidemiological and phenotypic differences (2).

Etiopathogenesis. The pathogenesis of IBD is not fully elucidated, this implying the interaction between a number of such elements as individual genetic predisposition, environmental factors, immunological factors and intestinal microbiota.

Genetic factors. Studies on monozygotic twins have shown a concordance rate of 40% for CD and 10% for UC. Approximately 10-20% of IBD patients have family members with the same disease, the risk of disease among first degree relatives being of 7% (1, 2). Genomic studies have identified over 200 susceptibility loci for IBD, the transmission being polygenic, and the most commonly known polymorphism being that in NOD2/CARD15 gene (3).

Environmental factors. The Western diet low in fiber, high in processed foods rich in carbohydrates and fats, stress, the use of oral contraceptives and non-steroidal anti-inflammatory drugs, all increase the incidence of IBD in developed countries. Smoking and appendicectomy are protective factors against UC but are considered risk factors for CD. Often the development of UC can be triggered by quitting smoking.

Immunological factors. The gut mucosal immune system has an increased level of tolerance to food or bacterial antigens. At the time of contact with a foreign antigen, Th-1 lymphocytes produce proin-

flammatory cytokines, such as gamma interferon and IL-2. In its turn, Th-1 will activate through cytokines the macrophages that release other pro-inflammatory cytokines: tumor necrosis factor-alpha (TNF-α), IL-1 and IL-6, thereby amplifying the inflammation. Chemokines control the recruitment of numerous circulating cells at the site of inflammation, with the release of prostaglandins, leukotriene, oxygen-free radicals, proteases and nitric oxide that will amplify tissue destruction. In the normal gut, the Th-2 lymphocyte-mediated inhibition mechanism becomes immediately active, and with the help of anti-inflammatory cytokines like interleukin-10 and TGF-beta inhibits Th-1 and macrophages, stimulating mucosal healing (4, 5).

The therapeutic response to corticosteroids or anti-TNF may provide evidence of the immune pathogenesis of IBD.

1. Intestinal commensal flora. Microbiota composition is highly diversified among individuals, but generally similar in the same species. Intestinal microbiota represents an ensemble of more than 10 trillion microorganisms that colonize the digestive system, including approximately 1,000 species of bacteria, viruses and fungi with more than 1 million genes, 150 times more than human genome. One-third of the intestinal microbiota is common to most people, but two-thirds are specific to each individual, demonstrating the different responses of patients to pathogens and treatment. Vaginal birth plays an essential role in gut colonization with commensal bacteria, *by crossing*/through the direct contact with the pelvic genital tract and then with maternal perineal area. Thus, babies born vaginally have different gut bacteria than those delivered by cesarean section.

Typically, the composition of intestinal microbiota in babies delivered by cesarean section is less diverse but is characterized by a high interindividual variability (6). As the infant consumes increasingly more complex dietary substrates, the gut microbiota undergoes changes. It tends to be relatively stable throughout early childhood (7). Two major microbial phyla - Firmicutes and Bacteroidetes - account for 99% of the bacteria in the gut. Despite its high interindividual variability, the gut microbiota shows a high functional uniformity regardless of age or sex (8).

2. Structure of the intestinal flora. Intestinal microbiota contains more than 1000 different species of microorganisms, weighing about 1 kg. The proximal part of the digestive tract, the stomach and small intestine are less populated by bacteria_due to the low oxygen concentration at these levels. Most of the microorganisms colonize the large intestine. The vast majority of bacteria belong to two classes: *Firmicutes* and *Bacteroidetes*.

From an anatomical point of view, bacterial species are distributed as follows: in the stomach there are normally between 0-100 bacteria of the genera *Lactobacillus*, *Candida*, *Streptococcus*, *Helicobacter*, *Peptostreptococcus*; the duodenum and ileum contain approximately 100 bacteria of the *Streptococcus genus/* Streptococcaceae and *Lactobacillus genus/* Lactobacillaceae families. Starting from the proximal ileum up to the colon, the bacterial population begins to increase in number and vary: at the level of proximal ileum there are 1000 bacteria of the genus *Streptococcus* and *Lactobacillus*, in the distal ileum 10^7-10^8 bacteria of the genera *Clostridium*, *Streptococcus*, *Bacteroides*, *Actinomycinae*, *Corynebacterium*, and in the colon 10^{11}-

10^{12} bacteria of the families *Bacteroides/* Bacteroidaceae, *Clostridium* groups IV and XIV, *Bifidobacterium/* Bifidobacteriaceae and *Enterobacteriaceae*.

Normally, a healthy human intestine hosts 10^{14} microbes-10 times the number of cells in the human body (9). Due to the major and bidirectional influence, the intestinal microbiota has a significant impact on the host and also the host influences bacterial adaptation and evolution. The relationship between the host and intestinal flora is extremely complex and important, and thus the assertion "the gastrointestinal microflora, especially that gained in the initial period of life, influences so deeply the morphological and physiological characteristics of its host, that many of the characteristics of the adult, which appear to be the expression of genetic endowment, are determined in reality by its microbial environment" is supported today by the existence of more and more disorders problematic in terms of therapeutic possibilities and patient response. Especially in the intestine, microbiota influences the structural development of lymphoid tissues, ensures the integrity of the epithelial barrier, the function and development of innate and acquired immunity (9).

Factors influencing the intestinal microbiota

Bacterial interactions. Bacterial interactions can act either antagonistically or synergistically trough the low secretion by aerobic bacteria of oxidation-reduction compounds, which will favor the growth of anaerobic microorganisms, enzymatic mechanisms and the production of growth factors.

From an antagonistic point of view, the barrier effect that is of particular importance to prevent digestive tract colonization with exogenous bacteria is highlighted. Due to the fact that in the intestine the commensal flora occupies some specific spaces, the exogenous microorganisms cannot penetrate. This effect can be exerted both between different species and within the same bacterial species. One of the characteristics of this barrier is the rapid elimination, by peristalsis, destruction, of the bacteria that try to penetrate the intestine.

Of importance for clinical practice is the fact that the barrier effect can be reversed in the course of an infection with pathogenic bacteria, which has several advantages through the virulence factors and do not have regular clearance, and thus may cause various diseases through changes in commensal flora structure "because of host-related factors that allow transient colonization with non-pathogenic species" (10).

Adhesins (bacterial adhesion factors) play a major role in bacterial colonization. These are proteins that recognize a certain carbohydrate sequence in the structure of glycoproteins or glycolipids present in the cell membranes, and which allow bacteria to adhere to the surface of the mucosa they colonize (7).

Host dependent factors. The relationship between the intestinal microbiota and the human body is symbiotic, reflecting a dynamic balance in order to maintain a physiological bacteriological structure of the digestive tract and, more precisely, a state of *eubiosis*.

Factors that keep the intestinal bacterial population under control are saliva, gastric acid secretion, self-defense capacity of the small intestine through mucus secretion, enzymatic activity, intestinal immune system, normal intestinal peristalsis and ile-

ocecal valve.

Saliva, through lysozyme, has an antibacterial role against the proliferation of bacteria belonging to of *Lactobacilli, Staphylococci, Streptococci* species.

Gastric acid secretion prevents the development in the digestive tract of exogenous bacteria originating from food or having the source in the secretions of the upper respiratory and digestive pathways. At the same time, gastric secretion is sensitive to acid-sensitive bacteria, which is demonstrated by the different structure of the intestinal flora in a patient with normo- or achlorhydria.

The self-defense capacity of the small intestine is the most important mechanism against the proliferation of exogenous bacteria. This self-defense capability is represented by gastrointestinal mucus (physical barrier to bacteria and their toxins) and intestinal mucosa participating in the defense process through innate and acquired immunity. In the case of gained immunity, secretory IgA, and IgG and IgM antibodies are secreted, which contain bactericidal antibodies and thus highlight specific responses from the gastrointestinal immune system. On the other hand, innate immunity produces in the gastrointestinal tract a group of antimicrobial peptides called defensins. The defensins in the human body are alpha and beta type; Paneth cells in the small intestine contain alpha-defensins and have bactericidal activity against *Listeria monocytogenes, E. coli, Salmonella typhimurium, Candida albicans* (6, 8, 9).

Normal intestinal peristalsis is an important mechanism of bowel clearance that counteracts the development of a pathogenic flora at this level by transporting the food and bacteria distally and thus preventing stagnation and multiplication.

Beneficial effects of intestinal flora at local and systemic level

Morphological effects. The host-flora interaction has a major impact on the morphology of intestinal mucosa, through antigenic stimulation, which can confer the digestive mucosa the appearance of chronic inflammatory response (3).

Immunological effects. Intestinal microbiota is involved in immune system homeostasis, so the body has the ability to tolerate the microorganisms it comes into contact with. Intestinal flora is the stimulus for the maturation of the immune system, by involving humoral and cell-mediated immunity, contributing to the expression of class II of the major histocompatibility complex molecules, development of a normal antibacterial humoral immunity, as well as of physiological tolerance to soluble intraluminal antigens: microbial or viral (1, 7).

The intestinal mucosal surface is one of the main entry points of pathogens into the human body, but in the healthy state the cells of the intestinal wall mucosa, interact with those of the commensal microbial flora, providing an effective barrier against pathogenic microorganisms. Intestinal epithelial barrier, consisting of a continuous layer of epithelial cells, closely attached to each other and in contact with the immune cells that underlie lamina propria (organized lymphoid tissues, Peyer plates), mucus-producing cells and overlapped mucus layer together with the commensal microbiota form a complex that protect the host against pathogen invasion, colonization and superinfection. For a long time, it was considered that the role of the thick mucin layer was exclusively of limiting the exposure of epithelial cells to microorganisms. However, an active functional role of

mucin in immunity has been demonstrated, aiding the recruitment of luminal antigens by the subjacent dendritic cells (DC) through a layer of small intestinal mucus gates and the depreciation of inflammatory responses of DC to bacterial antigens by co-stimulation with hyperglycosylated MUC2 mucin.

The commensal intestinal microbiota is an important obstacle against pathogen invasion through several mechanisms, including the struggle for metabolic growth substrates, production of antimicrobial compounds, occupation of intestinal niches and potentiation of host immune responses (i.e. the production of IgA and IgM) (8). A well-controlled and regulated bacterial contact is essential for maintaining an optimal immune function at the intestinal level. Similarly, intestinal microbiota, in particular through the production of butyrate resulting from fermentation processes, contributes to intestinal wall integrity, providing approximately 50% of intestinal mucosa energy needs, thus ensuring both the optimum proliferation of mucous cells and the epigenetic adjustment of cellular differentiation and apoptosis.

Understanding how intestinal microbiota modulates the intestinal immune system is the result of studies on murine models that have shown that the lack of antigenic stimulation leads to underdevelopment of gut-associated lymphoid tissue (GALT), as well as of systemic immunity, including impaired development of lymphoid organs, impaired recruitment and differentiation of lymphocytes. These alterations ultimately lead to the occurrence of immune-mediated inflammatory diseases (9, 10). It has been shown that, in humans, antibiotic treatment during childhood results in a higher risk of developing conditions such as: allergies, asthma and IBD (6, 9).

Human gut microbiota is a constant stimulus for the host immune system. To cope with this diversity, the host immune system recognizes only certain highly preserved phylogenetic antigens. This recognition is mediated by epithelial cells (EC) at the mucosal surface and dendritic cells (DC). The underlying dendritic cells play an important role in differentiating the naïve T cells in the mesenteric lymph nodes (MLN) into regulatory T cells that subsequently express proteins in the gastrointestinal mucosa where they mediate immune homeostasis (5, 6). It also directs T Helper cell responses to Th1 and Th2. Th1 immune responses are dependent on IL-12 production and are characterized by the production of interferon (IFN)-γ and IL-12. Th2 responses involve IL-4, IL-5, IL-6 and IL-13 with important role in humoral immunity. DCs can induce differentiation of regulatory T lymphocytes, with an important role in immune response modulation (6).

The bacterial components recognized by the host are usually nucleic acids, cell wall fragments via microbial antigen receptors, recognition receptors (PRRs) which recognize molecular motifs shared by different types of microbes, such as pathogen-associated molecular patterns (PAMPs), or surface molecule-associated molecular patterns, such as teichoic acid, polysaccharides, flagellin, DNA and double-stranded RNA. These microbial components serve as elements for differentiation of microorganisms by the immune system. Moreover, intestinal mucosal microorganisms appear to possess many different channels of communication with the host immune system and activate different PRRs, resulting in synergistic action and functional redun-

dancy between PRRs (5, 6, 8). PPRs include toll-like extracellular receptors (TLRs), Nod-like receptor family and the CD14 receptor for bacterial lipopolysaccharide. TLRs are signaling PRRs, which activate the transcription factor NF-κβ and recognize cell wall components of Gram-positive and Gram-negative bacteria, such as lipopolysaccharide (TLR-4), teictoic acid, and peptidoglycan (TLR-2) and bacterial flagellin, a common feature of intestinal pathogens (TLR-5) and unmethylated CpG DNA (TLR-9). Unlike TLRs, Nod proteins occur cytoplasmically rather than on the cell surface, allowing recognition of intracellularly translocated microbial components. Three important Nod-like receptors, namely Nod1, Nod2 and IPAF factor are encoded by caspase recruitment domain (CARD)4, CARD15 and CARD12, respectively. Nod1 recognizes gamma-D-glutamyl-meso-diaminopimelic acid, a peptidoglycan degradation product; Nod2 binds to muramyl dipeptide (MDP) - another peptidoglycan component - and IPAF binds to flagellin. Nod1 and Nod2 domains interact with receptor-interacting protein 2 kinase (RIP2/RICK) that mediates inhibitor kappa B (IκB) activity and NF-κB-dependent gene expression of proinflammatory cytokines. Certain microbial ligands can be identified by several PRR receptors. Typical examples are bacterial flagellin and peptidoglycan, which can be recognized by TLR5 and TLR2, respectively on the cell surface and by intracellular IPAF and Nod. Toll-like extracellular receptors have been shown to release cytokines from myeloid cells, resulting in the amplification of the resulting immune response. Stimulation of PRRs immediately triggers the activation of signal cascades for antimicrobial immune responses and downstream transcription of inflammatory modulators. Therefore, by recruiting/stimulating immune effector cells through signaling molecules and antigen presentation by DCs to B cells and MLN T cells, and by mucosal IgA production respectively, it can be argued that both innate immunity as well as the acquired one are activated. Detection of PRR-PAMP in the gastrointestinal tract also has the function of maintaining immunological tolerance and intestinal homeostasis (10, 11).

Therefore, dysbiosis can cause abnormal immune responses, thus being correlated in recent years with a variety of autoimmune and allergic diseases. Garett and al. demonstrated by a study on murine models that the depletion of the T-bet transcription factor in the RAG resulted in the development of spontaneous colitis. This suggests that microbiota is sufficient to induce intestinal inflammation (9). According to findings from animal studies, but also in humans, inflammatory bowel diseases (IBD) have been associated with dysbiosis. Children living in developing countries and which come in contact with a larger intestinal bacterial diversity have a lower incidence of inflammatory conditions in adulthood, including IBD. Statistically significant relationships have been also found between early exposure to antibiotics and the occurrence of IBD in these individuals in adulthood (2, 5, 12).

It has been shown that the continuous sampling of antigens and their presentation to naïve T-cells leads to the development of adaptive immunity to microbial invasion of the intestinal mucosa. Recent studies have shown that butyrate and propionate can inhibit histone-deacetylase (HDAC) not only in colon cells, but also in DC, through a mechanism involving the sodium-coupled

monocarboxylate transporter SLC5A8. According to current findings, butyrate and propionate block DC maturation and therefore inhibit the intestinal immune response and inflammation, through a DC mechanism dependent on SLC5A8 and HDAC. It has been shown that intestinal commensal bacteria are necessary to induce the expression of the short-chain fatty acid (SCFA) transporter SLC5A8 for DCs. (13, 14). DCs are involved in the potentiation of immune responses and increased antigen uptake by inducing the TLR expression (9).

Dysbiosis and inflammatory bowel disease

The native, resident microbiota is acquired in the first year of life and is a unique combination for each individual, such as digital footprint. Transient microbiota colonize the intestine and consists of pathogenic and non-pathogenic organisms.

Colon microbiota plays an essential role in the body by its participation in the achievement of important functions such as: prevention of pathogenic microorganism invasion, improving the function of intestinal cells, strengthening the immune system, vitamin synthesis, stimulate intestinal peristalsis to ensure transit and reduce unpleasant discomfort and bloating, avoiding inflammatory bowel processes (15).

Bacteria which are in colon microbiota composition are classified into several categories depending of their function: - Immunomodulatory microbiota: regulates the functioning of the intestinal immune system; - Protective microbiota: prevents colonization by pathogenic bacteria; - Muconutritive microbiota: maintains the integrity of the intestinal mucosa; - Proteolytic Microbiota: is beneficial in a small amount but harmful in a large amount. They are joined by lees which have a minor beneficial role but are harmful when forming the micelles.

However, there are other species, which are not numerically significant, but are important for homeostasis: *Proteobacteria*, *Actinobacteria*, *Fusobacterium* and *Verrumicrobia*.

In IBD patients, quantitative changes were revealed in bacteria belonging to the classes of *Firmicutes, Bacteroidetes, Actinobacteria, and Proteobacteria* (16, 17). For example, a reduction in the Clostridiales species of the *Firmicutes* class is observed in the fecal microbiota of patients with IBD (5, 8, 10, 18). An increase in *Ruminococcus gnavus* in the fecal microbiota was also observed among these patients. Other bacteria considered "beneficial" for the host have been shown to be reduced quantitatively in the fecal microbiota of these patients. An increased amount of bacteria of *Streptococcus* genus has been observed, as opposed to *Ruminococcaceae bacteria* (genus *Faecalibacterium*), which appear to be particularly deficient, especially in patients with CD. Salem *et al*. demonstrated in a recent study, using molecular methods for identifying bacteria, that *Faecalibacterium prausnitzii* was one of the most deficient species of *Faecalibacterium* genera in MAM of IBD patients (compared to healthy subjects) (19). As common elements, both in patients with CD and in those with ulcer hemorrhagic rectocolitis (UHRC), a decrease in *Clostridium, Coprococcus, Eubacterium* genera (*Firmicutes* class) was highlighted. Through studies in which both bacterial cultures and molecular methods were used, an increase in the population belonging to *Bifidobacterium* genus, highlighted in the fecal microbiota, as well as in intestinal mucosa biopsies of patients with IBD, and especially in patients

with CD was shown. Also, in many CD patients an increase in abundance of the bacterial population from the *Enterobacteriaceae* family, *Escherichia* and *Shigella* genus was identified (6, 8, 10).

Metabolic effects and the role of short-chain fatty acids in inflammation

The metabolic activities of intestinal microbiota are multiple and complex, acting as a "metabolic body" through the synthesis of vitamin B12, folic acid, vitamin K, proteins (hydrolysis, amino acid degradation), lipids (lipid hydrolysis, synthesis of long-chain hydroxylated fatty acids.

Action is also observed on endogenous products (deconjugation, dehydroxylation, dehydrogenation of bile acids), deconjugation of bilirubin and conversion of bilirubin into urobilinogen, cholesterol degradation, deconjugation of sex hormones (ensuring enterohepatic circulation), urease activity (ammonia production) and it produces pH changes and a decrease in redox potential (10, 20). In other words, the intestine is a multifunctional organ involved both in immunity and metabolism.

The intestinal epithelium has two differential gene networks, one regulating immunity and the other governing the lipid metabolism, the two being inversely expressed.

SCFAs are the end products of bacterial metabolism, mainly derived from the anaerobic fermentation and hydrolysis of polysaccharides and undigested proteins, which exert important physiological effects (8, 10). The main SCFA products of the colon are acetate, propionate and butyrate in a ratio of 2: 1: 1. They can be absorbed by the host, securing up to 10% of the basic energy needs. While acetate is used in cellular respiration and cholesterol synthesis in the liver and brain, propionate and butyrate are mostly used by colonocytes and liver as a source of energy. SCFAs may influence the recruitment of leukocytes, in particular neutrophil chemotaxis, by binding to the coupled receiver to protein G (GPR 43) and activation of protein kinase (MAPK), of protein kinase C (PKC) and transcription factor (ATF-2) (8, 10). SCFA, particularly butyrate, has been shown to reduce the production of monocyte chemoattractant protein-1 (MCP-1) an important factor that binds to monocytes and macrophages. Macrophages play a role in the secretion of proinflammatory mediators in chronic inflammation states, such as insulin resistance and obesity, atherosclerosis and also rheumatoid arthritis and neurodegenerative diseases, as well as in IBDs. Therefore, the production of MCP-1, IL-6 and INF-γ by intestinal epithelial cells influences the inflammatory and immune response of intestinal SCFAs, particularly butyrate and propionate, also reduce proinflammatory cytokines such as TNF-α and nitric oxide (NO) in neutrophils. SCFAs also influence phagocytosis and the production of reactive oxygen species by neutrophils and macrophages (10).

Studies on microbiota open up new perspectives on autoimmune diseases, proving that the microbiota is closely associated with host immune system, this interaction being based on epigenetic mechanisms. This way, new therapeutic strategies and more sensitive and specific biomarkers and potential therapeutic targets can be developed.

EDITORIAL

MALNUTRITION, SARCOPENIA AND FRAILTY IN LIVER CIRRHOSIS

Cirrhosis is the end stage of chronic liver diseases, associated with high mortality, and responsible for about 170,000 deaths yearly in Europe alone as reported by the World Health Organization (1), as well as the second cause of death associated with digestive diseases, after colorectal cancer (2). It is well known that cirrhotic patients are particularly prone to the development of malnutrition which has been shown to be an independent predictor of survival in these patients (3), mortality increasing in direct proportion to the severity of malnutrition, reaching almost 80% in those with sarcopenia and frailty (4, 5). Consequently, all patients with cirrhosis should be screened for malnutrition in order to diagnose this complication and its degree of severity.

Malnutrition is common across patients with liver cirrhosis, with an estimated prevalence of 40% in compensated cirrhotic patients and more than 95% in those with decompensated cirrhosis (4). In general population, malnutrition is defined as loss of muscle mass, while in patients with liver cirrhosis, malnutrition is defined as loss of skeletal muscle mass and body weight, decreased subcutaneous and visceral fat mass.

By definition, malnutrition occurs when diet is poor (decreased protein, fat and carbohydrate intake), unable to provide the necessary number of calories to maintain nutritional status or secondary to malabsorption due to liver disease and exocrine pancreatic insufficiency. In addition to poor dietary intake and malabsorption, there are several other causes of malnutrition in cirrhosis such as low protein synthesis, increased intestinal loss, cirrhotic hypermetabolism (hypermetabolic state is present in at least a quarter of cirrhotic patients), small intestine bacterial overgrowth, and gastrointestinal dysmotility (6). Decreased nutrient intake in patients with decompensated liver cirrhosis can also be accounted for by anorexia ─ a symptom that is present in over 90% of patients ─ early satiety related to compression from ascites (7). It should be underlined that the most frequent form of malnutrition in cirrhotic patients worldwide is poor nutritional status.

According to some studies, alcoholic cirrhosis is associated with more severe nutritional state than virus-related cirrhosis, and the malnutrition is more common in cirrhotic men than in women (8, 9). Several studies have reported that malnutrition in cirrhotic patients is correlated with the severity of liver disease and particularly with the development of complications such as hepatic encephalopathy, hepatorenal syndrome and ascites (10).

Assessment of nutritional status in cirrhotic patients should include a complete medical history (weight and appetite fluctuations, dietary intake, nausea, vomiting, and diarrhea episodes) and physical examination (to detect ascites, peripheral edema, muscle wasting and subcutaneous fat loss). Subjective Global Assessment (SGA) combines several elements of nutritional assessment among which muscle wasting is considered the most important (11).

SGA is recommended by the European Society of Parenteral and Enteral Nutrition (ESPEN) as a practical bedside method to evaluate the nutritional status in cirrhotic patients. The SGA method allows us to easily classify the severity of malnutrition in 3 grades: 1 (mild), 2 (moderate), 3 (severe) (11). In addition, there are several other clinical methods for assessment such as mid-arm circumference, hand-grip strength, and skinfold. The International Society for Hepatic Encephalopathy and Nitrogen Metabolism (ISHEN) recommended The Royal Free Hospital – Nutritional Prioritizing Tool (RFH-NPT) as the method to evaluate nutritional risk of cirrhotic patients (12). The RFH-NPT score was reported to correlate with severity of disease, clinical complications and survival (13).

Sarcopenia, defined as generalized loss of skeletal muscle mass, strength, and function, is widely prevalent in patients with liver cirrhosis, affecting more than 70% of these patients (14). In addition, sarcopenia is a progressive disorder, leading to physical disability and increased mortality related to respiratory and cardiac muscles involvement (15, 16).

In adults, a 0.5% loss of skeletal muscle mass occurs annually, this percentage rising after the age of 65, so that by the age of 80 an individual has only 40% of his/her peak of muscles mass (17).

In addition to sarcopenia of skeletal muscle, cirrhotic patients may present cardiac sarcopenia, characterized by left ventricular dysfunction in the absence of any overt cardiovascular disease (16), and respiratory sarcopenia increasing the risk of lung infections (15). The prevalence of sarcopenia in cirrhosis is much higher than in other chronic disease due to metabolic complications induced by hepatocellular failure.

There are several diagnosis methods in sarcopenia. Muscle wasting, defined as the progressive and generalized loss of muscle mass is the main clinical diagnosis criterion, whereas skeletal muscle cross-sectional imaging with computed tomography (CT) or magnetic resonance imaging (MRI) is the gold standard objective method for diagnosis (18). Functional evaluation of sarcopenia includes hand grip strength and 6-minute walk test (19).

Frailty can be defined as multi-system impairment associated with increased vulnerability to stressors (20). There is a significant overlap between sarcopenia and frailty, defined by Fried et al, both conditions including low gate speed and low grip strength as well as weight loss, self-reported low physical activity and exhaustion (21). The most reliable method for measuring frailty in clinical practice is the Fried Frailty Phenotype which combines five elements: exhaustion, slow gait speed, unintentional weight loss, low physical activity, and weak hand grip strength. A score of 0 is non-frail, 1 to 2 is defined as pre-frail and 3 to 5 is defined frail.

The management of malnutrition, sarcopenia and frailty improves survival and quality of life in cirrhotic patients. The European Association for the Study of the Liver (EASL) Clinical Practice Guidelines on nutrition in chronic liver disease recommends in cirrhotic patients at least 35 kcal/kg daily, with a 1.2-1.5 g/kg protein intake and supplementation with branched-chain amino acids (BSAAs) (22). It should be noted that this recommendation is not in line with the traditionally protein- restricted diet in cirrhotic patients aiming to avoid the risk of developing hepatic encephalopathy.

However, according to ESPEN only cirrhotic patients with stage III or IV encephalopathy require restricted protein intake (11). Oral intake should be recommended in all patients, and when this is not possible, artificial nutrition may commence either through a nasogastric, nasoduodenal or nasojejunal tube (enterally) or intravenously (parenterally).

The management of malnutrition in clinical practice includes the use of the BSAAs leucine, isoleucine and valine administered orally, enterally or parenterally. Although some studies have reported improvement in the degree of encephalopathy, their usefulness remains controversial, as according to ESPEN, enteral feeding enriched with BCAAs should be reserved to patients who develop encephalopathy with enteral feeding despite appropriate treatment.

Finally, the management of malnutrition, sarcopenia and frailty in patients with liver cirrhosis should include physical activity and exercises tailored to the patient's ability, beginning with moderate intensity, to improve muscle mass and function (22).

However, long-term studies are needed to demonstrate that by combining nutritional needs (at least 35 kcal/kg daily, 1.2-1.5 g/kg daily protein intake) and physical activity, we can achieve growth in muscle mass and function, as well as in the survival rate of such patients.

NEWS

HYPERHOMOCYSTEINEMIA IS AN INDEPENDENT RISK FACTOR FOR INTRACRANIAL ATHEROSCLEROTIC STENOSIS

Stroke has become one of the main causes of disability and death among the population. Intracranial atherosclerotic stenosis (ICAS) is the most common cause of stroke. It is essential to identify, prevent and treatment he modifiable risk factors of ICAS. Hyperhomocysteinemia (HHcy) is considered a risk factor for cardiovascular disease and atherosclerosis. In addition, the exiting data in literature on the existing literature on the relationship between serum homocysteine level and stroke is still controversial. A new study published in *AGING* examines the association of homocysteine concentration with ICAS. According to statistical and processing data, HHcy could be an important marker of vascular injury and a potential target for the prevention of vascular injury, especially for intracranial artery. Therefore, the research group´s conclusion was that increased homocysteine may be an independent risk factor for intracranial atherosclerotic stenosis (Ying Liu,Jing-Hui Song, Xiao-He Hou et al.Elevated homocysteine as an independent risk for intracranial atherosclerotic stenosis. *Aging* 2019, Vol. 11, No. 11).

COVID-19 AND CARDIOVASCULAR STORM

COVID-19 pandemic is one of the biggest challenges confronting communities and nations, having a tremendous impact on public health services all over the world. In the past years, people have faced several worldwide epidemic infections, such as Severe Acute Respiratory Syndrome (SARS), avian influenza, influenza, but SARS-Cov-2 is rapidly becoming the most threatening global enemy, endangering not only the health systems' stability, but transforming into a social and economic crisis.

SARS-CoV-2 is part of a group of viruses, including severe acute respiratory syndrome CoV (SARS-CoV) and Middle East respiratory syndrome CoV (MERS-CoV) (1), well known in the past two decades and infecting almost 9,000 people worldwide (2).

Coronaviruses are single stranded RNA, presenting (when symptomatic) with almost the same symptomatology, consisting of fatigue, fever, and dry cough at the beginning (3). The severity of symptoms, alone or in combination with modified blood biochemistry represent prognostic markers in COVID-19 patients (4) and they may vary from absence of symptomatology or mild pneumonia to severe respiratory impairment: dyspnea, tachypnoea, low blood oxygen saturation or lung infiltrates in 24-48 hours.

The severity of lung injury may lead rapidly to acute respiratory distress syndrome (ARDS), an entity that is usually associated with high mortality rates since the early reports from the American-European consensus conference in 1994 (5), despite new ventilation protocols with new generation of ventilators.

The ARDS evolution may be complicated by respiratory failure, septic shock, or multiple organ dysfunction with an increased risk of death. Moreover, studies suggested that in ARDS, cardiovascular complications such as fulminant myocarditis and vascular thrombotic events should be considered (6).

COVID-19 and cardiovascular complications

The thrombogenic status in COVID- 19 creates the premises of developing pulmonary thromboembolism, acute myocardial infarction, or strokes. Since February 2020, several studies reported a high incidence of myocardial involvement in critically ill patients with COVID-19 with or without previous cardiac impairments (7).

Previous conditions may represent risk factors for the infection with the new coronavirus (8), data confirmed also in a systematic review that included 41 studies and 27670 patients which demonstrated the higher risk of death in patients with preexisting cardiovascular diseases, immune and metabolic disorders, respiratory diseases, neoplasia, cerebrovascular, renal, and liver diseases (9).

The main target of SARS-CoV-2 is represented by ACE2 receptors, that are highly expressed in the lungs and heart, a mechanism that rapidly became controversial in terms of using or not Angiotensin Conversion Enzyme Inhibitors (ACEIs) or Angiotensin Receptor Blockers (ARBs) in COVID-19 hypertensive patients. This discussion was clarified by the most recent guidelines recommendations, which stated that the use of ACE inhibitors is safe and

should be continued as indicated (10).

In a systematic review and meta-analysis that analyzed 27 studies with 10197 patients taking renin-angiotensin drugs in COVID-19 there was nonsignificant associations between ACEIs/ARBs and death or ICU admission, risk or severity of SARS-CoV-2 infection and hospitalization, but a significant association between RAAS drugs usage and hospitalization was found, in the subgroup analyses of the United States of America included studies (11).

Furthermore, there are several studies that show higher rates and severity of the infection in men versus women due to a higher expression of proteins that bind the virus and genome disparities (12), meanwhile a study performed in the United States of America revealed racial and ethnic disparities, African American/Black and Hispanic populations having a higher rate of SARS-CoV-2 infection and mortality compared with non-Hispanic White population, but with similar rates of case fatality (13).

COVID-19 and
acute coronary syndromes

When acute coronary syndromes are taken into consideration, the endothelium plays a major role. It provides normal vascular homeostasis by regulating vascular tone, cells adhesion, thrombosis, and inflammation, meanwhile lymphocytes represent a major regulatory point in maintaining homeostasis and against exaggerated inflammation after infection (14).

Therefore, due to the intense activation of endothelium caused by a high number of cytokines associated with low levels of T-lymphocyte lines, the COVID-19 patients present an increased prothrombotic status associated with an intense inflammatory response (15).

The magnitude of the inflammation is well corelated with the cardiac involvement, which can be revealed by high levels of troponin and NT- pro BNP at admission. In consequence, these patients present a high risk of coagulopathy, heart failure or a mortality up to 50% (16).

Other biomarkers that can be used for therapy efficiency are endothelial extracellular vesicles (17) and endothelial progenitor cells, that can be also correlated with disease severity (18) and with vascular injury (19).

It is well known that atherosclerosis and inflammation represent important risk factors in developing acute coronary syndromes (20). But several studies also reported a relation between acute coronary syndromes and COVID-19 caused by coronary artery thrombosis, even without a pre-existing atherosclerotic lesion or with nonobstructive lesions (21), most likely due to microvascular involvement (22).

A study that included 305 patients with COVID-19 from 7 hospitals in New York City and Milan illustrates the significance of the cardiac involvement. Thereby, from the 305 patients included, 190 had evidence of myocardial injury and from them 26.3% had right ventricular dysfunction, followed by 23.7% with left ventricle wall abnormalities, 18.4% with left ventricle global dysfunction, 13.2% with diastolic dysfunction grade II or III and 7.2% pericardial effusions (23).

In terms of paraclinical methods, these patients require classical echocardiography, but cardiac MRI mapping techniques are particularly useful providing evidence of diffuse myocardial infiltration even in asymptomatic cases (24).

Regarding the acute coronary syndromes therapy strategies, the ESC Guidance for the Diagnosis and Management of Cardiovascular Disease during the COVID-19 pandemic stipulates that the invasive cardiac procedures in emergency situations, such as ST-

elevation acute myocardial infarction, non-ST elevation acute myocardial infarction in very high risk and high-risk patients and also in cardiogenic shock must not be postponed. The reperfusion therapy remains unchanged in terms of strategy in STEMI patients that must be managed as if they are COVID-19 positive in the absence of a previous RT- PCR test for SARS-Cov-2.

The reperfusion therapy remains the primary PCI, with a maximum delay from diagnosis to reperfusion of 2 hours, procedure that may be delayed no more than 60 minutes due to care and protective measures implementation. Fibrinolysis will be maintained as second option if the reperfusion target time cannot be achieved and if it is not contraindicated (25).

COVID-19 and arrhythmias

Several studies demonstrated the presence of cardiomegaly and right ventricle enlargement in COVID- 19 patients, with the presence of arrhythmias caused probably by myocardial infiltration and severe inflammation linked to ion channel dysfunction and both electrophysiological and anatomical remodeling (26).

Besides these, adding the pharmacological agents that COVID- 19 patients require, antiviral drugs such as Hydroxychloroquine and Azithromycin that are well known to prolong QT interval, requires a special attention. Repeated ECGs, electrolytes balance and kidney function are necessary and the combination with Amiodarone should be avoided. Moreover, all modifiable QTc prolonging factors must be corrected, including kalium and calcium levels, magnesium supplementation and bradycardia avoidance, with the necessity of ceasing concomitant QT- prolonging drugs if needed (23).

On the other side, elective procedures such as ablation or cardiac device implantation should be postponed, urgent procedures being performed only in exceptional cases.

COVID-19 and myocarditis

Myocarditis is well known to provide heart failure and sudden cardiac death (27), being also potentially caused by COVID-19.

There are four presumed mechanisms that may explain the cardiovascular involvement in COVID-19: a direct viral effect against cardiomyocytes, myocardial interstitial fibrosis, secondary hypoxia induced by pulmonary impairment and the inflammatory immune response that generates the cytokine storm (28).

Fulminant myocarditis represents a high mortality cardiac condition, in some registries with a short-term survival rate of only 58% (29), but with a higher long-term survival after discharge rate reported in some retrospective studies compared to non-fulminant myocarditis forms (30).

Chen *et al.* observed that in their center, which treats critically ill patients with SARS CoV-2 complicated by severe cardiac injury, the main cause of death was fulminant myocarditis. From the 120 patients included in the study, 27,5% had high levels of NT-pro BNP and 10% c Tn I (6).

In SARS-Cov-2 infection the virus binds on ACE2 receptors located in the myocardium and the endothelium, sometimes developing an overwhelming immune reaction that can lead to cytokine storm, with powerful damage of the endothelium that leads to multiorgan failure and death (31).

The risk factors and incidence of myocarditis in COVID-19 are still unclear, patients receiving in these cases anti-inflammatory therapy alongside with high dose parenteral glucocorticoid or even immunoglobulins, but standard care therapy may reach its limits, therefore mechanical circulatory support therapy may be neces-

sary for these patients. Adding venous-arterial ECMO (V-A ECMO) to standard therapy may cause a positive impact on patient's survival.

The first case of COVID-19 complicated by fulminant myocarditis reported in China was a male patient with high levels of troponin I, and NT pro BNP, with diffuse myocardial dyskinesia and a low left ventricular ejection fraction, successfully recovered after 3 days on ECMO (32).

Also, myocardial injury may be present even in convalescent patients with no previous cardiac symptoms or conditions (33).

In case of cardiogenic shock, if there is a suspected or positive COVID-19 patient, the European Society of Cardiology recommends prioritizing the health- care workers' protection, being also more restrictive with mechanical circulatory support; however, if needed, the use of ECMO should be considered. In case of negative COVID- 19 patients they will be treated as usual.

COVID-19 and pulmonary embolism

Even if pulmonary embolism is an uncharacteristic evolution of COVID-19, more patients present at the time of admission with both pathologies, coincidental or not (34).

The signs that must alert the medical team of an acute onset of a pulmonary embolism can be a sudden respiratory worsening, the occurrence of a new tachycardia , hypotension, hypovolemia or sepsis and ECG changes suggestive for pulmonary embolism or deep vein thrombosis signs revealed on clinical examination.

In a systematic review of 42 studies enrolling 8271 patients, deep vein thrombosis was found in 20% of the COVID-19 patients, meanwhile pulmonary embolism occurred in 13% of the cases. The study concluded with a pooled mortality rate of 23% in patients with thromboembolism versus 13% in patients without thromboembolism, showing an increased risk of death in COVID-19 associated with this complication (35).

The incidence of pulmonary embolism seems to be higher that it was thought and is revealed also in a study that analyzed 3011 patients, being the most common condition, with 198 cases (6.6%), followed by 55 patients with heart failure, 15 acute coronary syndromes, 14 ventricular arrhythmia, 4 endocarditis and 3 myocarditis. Even though the study showed a low incidence of cardiac complications during hospitalization (36), the high rates of pulmonary embolism must alert the medical team in a fast diagnosis and treatment in these patients. Another evidence showed the magnitude of venous thromboembolic embolism in COVID patients, translated in terms of survival, the incidence of severe condition being more likely to occur, especially in those with lower levels of lymphocytes (37).

But since other studies reported similar in- hospital mortality in critically ill COVID-19 patients with or without the presence of pulmonary embolism (38), further prospective randomized studies are needed.

The most common measures that must be taken in embolism prevention is to consider anticoagulation at standard prophylactic doses in all COVID- 19 patients. Also, due to several possible interactions between non-vitamin K antagonist oral anticoagulants (NOACs) and antiviral drugs such as Lopinavir or Ritonavir, the use of NOACs must be avoided, preferring the use of heparins instead. The risk stratification is accordingly to the current ESC guidelines.

Ongoing randomized clinical trials still represent the most powerful tool to provide high quality clinical care and offer best opportunities to manage the pandemic crisis and they started offering us the hope that we needed.

CONCLUSIONS

COVID-19 still represents a difficult enemy to deal with, but in the past weeks we started to see the light over horizon by developing vaccines and by continuously analyzing best specific and supportive treatments for the SARS-CoV-2 infection.

An important lesson learnt from the COVID-19 pandemic is that there must be a conjugated effort from the Heart Team, that now includes the infection disease doctor and the epidemiologist, in eradicating this virus and assuring the patient survival.

Only a persuasive collaboration between the entire medical team, patients, and health public policies alongside with every single social and economic aspect that is to be improved, may shape the victory against any health menace that may endanger humanity.

EDITORIAL

THE IMPACT OF COVID-19 PATHOLOGY ON THE SENIOR POPULATION

The outbreak of coronavirus in December 2019 has completely reshaped urban life due to the need to limit the spread of the disease and provide essential services to the city's most vulnerable residents, such as senior patients. Current epidemiology suggests that approximately 80% of patients with COVID-19 have mild symptoms, 45% have severe symptoms that require hospitalization, while 5% become critically ill, requiring mechanical ventilation. Differences in reactivity are due to the degree of viral load, the host's immune response and, more importantly, the patient's age in the presence of generic co morbidities (such as hypertension, diabetes, and thrombotic events), and geriatric syndromes (such as frailty, malnutrition, risk of falling, cognitive impairment) (1).

Older adults rank in the most at-risk segment of the population because the basal functional resilience is fading (2), and because it is physiologically associated with frailty, cognitive decline (3), and progressive alterations of motor performance (4). All these alterations intimately coexist in the frailty syndrome (5), which is known to be associated with disability, traumatic falls, and hospital admission (6). On top of that the wearisome settings of hospital wards provide poor incitements to the older patients and often aggravate nutrition-related or activity-related sarcopenia (6, 7). Multidisciplinary interventions, such as Age-Friendly Hospitals or the HEPAS approach (Healthy Eating, Physical Activity, and Sleep), are models for dealing with elders' multiple issues simultaneously. Despite this knowledge, contemporary society, and health services put the older adults in the background (8).

As expected, it became immediately evident that the majority of deaths from COVID-19 occurs in the older patients, especially in those suffering from two or more comorbidities, cardiovascular diseases, diabetes mellitus, chronic obstructive pulmonary disease, malignancy, and chronic kidney disease being the most frequent (9). Additional factors worsening the COVID-19 emergency within geriatric population may include intrinsic multidimensional features such as disabilities, cognitive and mood disorders, polypharmacy, social isolation, nutritional deficits, and extrinsic factors, such as widespread ageism, the generalized lack of geriatric culture and alleged errors in the management of long-term care facilities (10).

It is well documented that advanced age is frequently associated with impaired nutritional status and a recent meta-analysis indicates the prevalence of high malnutrition risk in Europe to be 28%, 17.5% and 8.5%, for hospital, residential care, and community settings, respectively (11). There are many causes that concur to malnutrition in older age, such as malabsorption, increased nutrient losses, augmented metabolic demands, and reduced dietary intake. Malnutrition is a major geriatric syndrome and an important cause for muscle wasting and weight loss, which is strongly related to frailty, sarcopenia, and negative outcomes (12, 13, 14).

Nutritional status influences the im-

mune system of senior population through impairment in cell mediated immunity, cytokine production and phagocyte functions. In addition, aging *per se* is characterized by a process of progressive dysfunction of several compartments of the immune system, named immunosenescence, which includes smoldering inflammation and immunodeficiency (10). The complex relationship between immunity and nutrition in older population is clinically relevant and negatively impacts antibody production, response to vaccination and susceptibility to infections (15, 16, 17). Notably, the altered response to vaccination should be seriously considered and evaluated by randomized control trials now, that an efficient vaccine against SARS-CoV-2 is available.

It is important to emphasize that both arms of the immune system are altered in elderly: decreased B-lymphocytes production (exposing to severe infections) and T-lymphocytes activity, decreased cell-mediated and humoral-mediated immune response (16, 17). Due to this age-dependent alterations of the immune system, a relevant percentage of older patients progresses to insidious systemic inflammation, mainly affecting the lung, heart, renal function, and coagulation system. This second stage of hyper inflammation is characterized by massive production of pleiotropic cytokines (e.g., IL-6) by lung resident (e.g., macrophages) and circulating immune cells (18).

In a retrospective, single-center study, performed in the Renmin Hospital of Wuhan University in Wuhan, China (19), that included 339 cases of COVID-19 over 60 years old, the data reported that lymphocytopenia was found in 211 cases (63.2%), and the counts of $CD4^+$ and $CD8^+$ cells were all decreased compared with normal values. Very old elderly (aged 80 years or above) was shown to increase the likelihood of death compared to young old patients (60-70 years old). Symptoms of dyspnea and the presence of co morbidities including cardiovascular disease, cerebrovascular disease and COPD were all predictive of fatal outcomes. SARS-CoV-2 caused a much more severe pneumonia in the aged people than younger patients. Of the 339 elderly COVID-19 patients included, over 70% were severe or critical, and the case fatality rate was 19% (19).

Cough and fever were the most commonly seen symptoms in patients with COVID-19 and were mortality risk factors (20). While cough was equally observed in all age-groups, fever was more likely to be absent in older patients. This phenomenon is not uncommon and is, perhaps overlooked. A recent study reviewing the clinical features of COVID-19 patients admitted to Hainan General Hospital found significant difference in the prevalence of fever between young, middle-aged, and elderly patients (1). It is likely because of the lower baseline body temperature in elderly due to aging (21, 22, 23) which may translate to a lower maximum temperature of fever (24). This suggests that the usual temperature threshold for fever should not be used as a case definition of COVID-19 in geriatric patients. In fact, a study on a total of 111 nursing home residents found that lowering the threshold for a clinically significant fever increased the sensitivity of detecting infections (22). However, it is not recommended to lower the temperature threshold in the case definition of COVID-19 in geriatric patients because an individual's baseline body temperature is also determined by a range of demographic

factors, comorbid conditions, and physiological measurements (21). To assist surveillance against the current pandemic, older patients should measure on a regular basis the baseline body temperature that can be used to define the threshold temperature for fever. If this is not feasible, a baseline body temperature of 36.5 degrees Celsius might be used instead (23).

There is compelling evidence that several nutrients, including vitamins (A, B group, C, D, E) and minerals (zinc, iron, selenium, magnesium, and copper), exert a key role in supporting the immune systems. Micronutrients contribute to the development and integrity of physical barriers, participate to neutrophil/macrophage maturation and functions, and play a role in modulating inflammation. Additionally, adaptive immunity is influenced by nutritional deficits, especially lymphocyte maturation and differentiation, memory cell generation, and cytokine and antibody production. Nutritional support has been shown to improve immune responses in older malnourished patients (10, 18, 25).

Zinc deficit is common in malnourished elderly individuals and it is related to increased risk of infections. Accordingly, adequate zinc support counteracts the alteration in the immune response through the enhancement of both total number and function of T cells (26, 27). Moreover, zinc supplementation has been reported to increase natural killer cell activity (28).

Vitamin A is a key factor for the development of the immune system, for epithelial and mucosal barrier generation, and contributes to support the efficacy of T cell-based viral vaccines (29). Vitamin E stimulates T cell function and confers protection against upper respiratory tract infection (30). Recent data supports that probiotics have a role in modulating the immune system, with probiotic supplementation recognized as an effective nutritional intervention (31).

Vitamin D modulates several aspects of the innate and adaptive immune system and its deficiency is highly prevalent in the elderly worldwide. Vitamin D supplementation appears to reduce the risk of infections through pathways that can reduce both viral replication and the production of pro-inflammatory cytokines. These are the reasons why it has been proposed to administer high doses of vitamin D in COVID-19 patients (10, 32, 33). A recent study that was performed in a nursing-home dedicated to old residents with physical disabilities and major neurocognitive and psychiatric disorders evaluated the effects of an oral bolus of 80,000 IU vitamin D3 administered either in the week following the suspicion or diagnosis of COVID-19, or during the previous month. The main finding was that bolus vitamin D3 supplementation during or just before COVID-19 was associated with less severe COVID-19 and better survival rate in frail elderly (34). A recent trial has assessed the effects of vitamin D supplementation on influenza vaccine response in elderly vitamin D-deficient subjects (35). Surprisingly, no effect has been detected on antibody production, thus concurring to underline the complex metabolic-immunological substrate of the geriatric population.

Vitamin C influences immunity through regulation of innate B and T cell proliferation and differentiation, their migration to sites of infection, and promoting antimicrobial activity and antibody production (10). It is well known that vitamin C tends to be depleted during infections, particularly in respiratory infections, and that is why

trials started to investigate the efficacy of intravenous vitamin C in COVID-19 patients. The data showed that administration of 15 g/day of IV vitamin C for 4 days may decrease mortality in older patients with complications such as sepsis-related ARDS (36). This new line of investigation is supported by a previous observation indicating a low severity of pneumonia in senior patients supplemented with vitamin C, especially in those with smaller initial concentrations (37).

Malnutrition, frailty, and sarcopenia are key factors in the increased risk of falls and fractures in older population. The frail seniors face a risk of 1.2 to 2.8 times for falls and fractures and a risk of 1.2 to 1.8 times for hospitalization. During the pandemic, surgery on subjects who suffered trauma from a fall was a matter of debate. In the post-COVID-19 era, the saturation of health services can only be the tip of the iceberg in relation to the dynamics of fragility, the COVID-19 pandemic causing a cycle of decline in functional capacity, with a higher risk of traumatic falls and hospitalizations for fractures on frailty in the near future (38, 39).

As with other diseases, COVID-19 shows atypical or peculiar manifestations in elderly patients. In the event of a new COVID-19 outbreak, the occurrence of sudden behavioral changes and subsequent *delirium* deserve special attention, as it may be considered a prodromal phase of the disease, especially in the presence of lymphopenia; widespread inflammation or hypoxia may appear later (40). It is possible that SARS-CoV-2 might have early and particularly harmful effects on the brain functions of older patients with dementia, manifesting as delirium which might be frequent in the prodromal phase of the infection when other typical symptoms have not yet emerged. As also suggested by other authors, (41, 42) we believe that a symptom-based strategy centered on the identification of typical symptoms is not an effective approach for preventing the spread of the virus in this specific population and should therefore be revised to include delirium and other atypical symptoms.

It has also been shown that older patients with Parkinson's disease and a history of lifelong psychiatric symptoms may be exposed to increased vulnerability to the stressful effect of the COVID-19 outbreak. Psychiatric characteristics are *per se* multimorbid, characterized by great intra- and interindividual variability in clinical presentation and can be greatly influenced by stressful events (43). The COVID-19 pandemic is an important stressor associated with exacerbation of psychiatric symptoms. Recent data have shown higher levels of psychological distress among the general population and an increased risk of recurrence and worsening in patients with neuropsychiatric disorders during the outbreak. As a result, recent preliminary reports have shown higher levels of stress, depression, and anxiety in patients with Parkinson's disease. The endangerment of the quality of life during social restrictions has also been confirmed (44, 45).

Depression turned out to be the most common psychiatric symptom reported by patients with clinical aggravation. Current findings suggest that interventions aimed at reducing mood irritability and instability, such as the use of mood stabilizers, could have an indirect effect on the health and well-being of older patients with psychiatric diseases during the pandemic (42, 44, 46, 47).

CONCLUSIONS

Aging comes with a multitude of psychological, social, and environmental vulnerabilities. Frailty in older adults carries the risk of various infections and decreases all forms of immune response, which makes the progression of the disease and the risk of death three times higher than in other age groups. In addition, seniors have multiple co morbidities and increased number of hospitalizations, which increases the chance of contracting the infection during a pandemic. They have cognitive and sensory deficits that make it difficult for them to understand and follow precautions. Many of them are institutionalized, being exposed to the risk of overcrowding, poor hygiene, and lack of adequate supervision. Pandemics have a significant psychosocial impact over them: anxiety, panic, adjustment disorders, depression, chronic stress, and insomnia are the main branches. Misinformation and uncertainty give rise to the massive alert.

In these contexts, the elderly are particularly vulnerable. Social distancing, although a major strategy for combating COVID-19 is also a major cause of isolation, especially in settings such as hospitals or nursing homes, as an independent risk factor for depression, anxiety disorders, and suicide.

While identifying methods to treat and prevent COVID-19 infection is an urgent priority, it is also important to consider that the current pandemic is the third major outbreak of a new coronaviral infection in humans in the last 20 years. However, the complex protection of the vulnerable senior population is still sorely missing, and strategies to address this issue should be a first and new intention.

CONTEMPORARY WITH THE PARADIGMS OF A PANDEMIC

The COVID-19 pandemic marked our existence, and for over a year we faced various experiences, some of them dramatic.

Over time, humanity has gone through such moments that have resulted in suffering, loss of lives, economic crises, and social change. Epidemiological theories predict that at an interval of 100 years pandemic events may evolve as a consequence of the phenomena of adaptation of microorganisms and the crossing of barriers between species, some of which cause devastating diseases in the human population. By prospecting the history of these events, in the last hundred years there have been several crisis events with a tendency towards the evolution of new pandemics or epidemic phenomena with pandemic risk. The Spanish flu pandemic in 1918 was followed by the Asian flu pandemic (1957), the seventh cholera pandemic (1968-1975), the Hong Kong flu pandemic (1968), the HIV/AIDS pandemic (since 1981), a new type of influenza A (H1N1) pandemic (2009), but also some epidemic events that had all the chances to evolve towards pandemic manifestations such as: the epidemic of acute bovine spongiform encephalitis with a tendency to spread to humans (1996), localized avian influenza A (H5N1) epidemics (1997), Severe Acute Respiratory Syndrome - SARS (2002/2003), Middle East Respiratory Syndrome - MERS (2021), West African Ebola epidemic (2013/2014), Zika virus infection (2015). All these culminated in 2019 with the entry into circulation of a new coronavirus, SARS-CoV-2, different in varying proportions from SARS (genetic similarity of 80%) or MERS (genetic similarity of 50%) (1, 2). These global alerts have surprised the often-unprepared population and an unfortunate experience was quickly forgotten for various reasons but especially by the fact that the 21st century has installed itself in an effervescence of changes through an alert pace of technology, population movement and information explosion.

Since the beginning of this COVID-19 pandemic, we have faced several paradigms. Starting from the definition of "paradigm" (a pattern or model, a system of rules and regulations, a set of specifications or criteria for setting boundaries), from December 2019 until now, we have experienced many paradigm shifts exemplified by changing to a set of rules to other rules, what was acceptable in the past will no longer be tolerated in the future, what was successful in the past will not be successful in the future.

The new EPIDEMIOLOGICAL PARADIGMS brought into discussion several aspects, some of them still remaining in the field of controversy. SARS-CoV-2 infection has been considered a less severe respiratory disease than influenza… but the mode of spread and the number of cases or deaths contradict this first presumption from the beginning of the phenomena (3). Transmission is direct and occurs through "droplet nuclei" with dimensions of < 5μm… but transmission through respiratory secretions is made directly during coughing, sneezing, speaking or singing but also indirectly through air currents that cause septic secretions, surfaces or contaminated objects because the persistence of the virus can last for hours and days (4, 5, 6). It was

considered that asymptomatic patients do not transmit the… virus, but the initial WHO statement was disputed by subsequent scientific evidence and epidemiological arguments. The increased rate of asymptomatic and presymptomatic (up to 40% of the infected population) contagious over a period of at least 14 days should be considered in establishing infection detection and control strategies (7, 8).

The virus reduces its circulation during the season by the fact that temperature and humidity can influence the viability of the virus through their effect on the properties of surface viral proteins and lipid membrane… but research using mathematical modeling methods, which introduced climate factors variables, have failed to establish with certainty that there is a direct link between the spread of the virus and high temperatures. The proof of the lack of braking effects of the high temperatures of the summer season for the circulation of the virus is direct and concrete by registering an increasing evolution of the number of cases in the months with high temperatures or in the territories with warm climate (9).

It was initially considered that only the elderly or adults with comorbidities are affected… but although these categories of people have a higher risk of developing severe forms of illness and death (the fatality rate is 10-27% in those over 85 years and 3-11% respectively at 65-84 years, compared to 1-3% for 55-64 years), severe forms were later reported in people without comorbidities, from young age groups, and regulations on the clinical management of cases emphasized the need to take into account the possible unfavorable development in young people and even children (10, 11). Thus, a paradigm shift has been established that any person, regardless of age or preexisting morbidity, should be considered at a potentially increased risk of developing a moderate to severe form of the disease.

Another paradigm shift started from the premise that natural collective immunization can be seen as a possible strategy to accelerate the limitation of the spread of the virus… but the early relaxation policy applied in Sweden and the United Kingdom through which schools and most jobs continued their activities, on the principle that the rapid natural immunization and as many people as possible will ensure a halt to the phenomenon, did not work (12). Approximately 6 months after the onset of the pandemic, low levels of seropositivity in the general population have been reported in most EU / EEA Member States. A study conducted in a region of Austria, which was severely affected, showed a seroprevalence of antibodies of 42% among its residents (1,500 people evaluated in week number 17) and in Spain, in a cohort of 60 983 people in the general population, the presence of IgM and IgG antibodies was identified in only 5% of those investigated (week 18-19) (13). By using models to assess the prognosis of the evolution of the pandemic, it was considered unlikely that the level of population immunity will reach, by winter 2020-2021, sufficient levels to achieve extensive protection (14), which time has shown. October - December 2020 the third pandemic wave brought back to a state of crisis and panic through the large number of cases but especially serious forms and deaths.

The new TECHNOLOGICAL PARADIGM has changed a lot the educational framework, the health systems and the business or economic environment. The education sector already used digital platforms at the beginning of the pandemic, which could make it more dynamic in the implementation of distance or hybrid edu-

cation. Telemedicine platforms are not new, but the COVID-19 crisis has shown the need to digitize this sector. E-Health and M-Health platforms (telemedicine through monitoring devices, mobile phones) with very different objectives proved to be necessary. These platforms can range from patient care activities, diagnostic or care medical management, etc. making possible several facilities such as: saving time, avoiding unnecessary transfers, optimizing resources and reducing costs. The limits of social contact, especially during lockdowns, have forced the implementation of operational and economic solutions through remote technologies in various sectors of life (15).

The new PARADIGM OF THE HEALTH SYSTEM has changed the concept of curative policies in infectious pathology based on the *"Pasteurian paradigm"* which states that every disease is due to a pathogen; for each disease there is a sure treatment that targets the cause responsible for its occurrence. The COVID-19 pandemic has triggered unprecedented measures worldwide, which have often been taken in an "emergency" manner. Alternatively, COVID-19 should be assessed as part of a global health problem that requires a "systemic approach" that allows interaction with other known and preventable health conditions that currently receive a disproportionately low level of attention. The shift from a specific reactionary paradigm to a "systemic paradigm", holistic, coordinated and preventive, has become a necessity in the current context. The globalized world is currently facing a "syndemic" - which means a synergy of epidemics that occur in different times and places, interact with each other to produce complex sequelae and have in common underlying social factors (16).

The examples are numerous, and the attention directed only to the virus has blurred the interest for capturing some essential changes in the personal life of each one as well as that of the community, in the demographic, political and social evolution of the whole humanity. The pandemic will be gradually brought under control but the question that needs to be concerned is whether these paradigm shifts in the COVID-19 pandemic have made us more competitive or better prepared for a possible new challenge.

NEWS

SCREENING OF MULTIPLE BIOMARKERS ASSOCIATED WITH ISCHEMIC STROKE IN ATRIAL FIBRILLATION

Atrial fibrillation (AF) is a common arrhythmia and constitutes a major health problem worldwide mainly because of its associated increased risk of stroke. In individuals with AF, the risk of ischemic stroke is substantially reduced by oral anticoagulation; however, residual risk remains. Several clinical characteristics are associated with an increased risk of ischemic stroke in patients with AF regardless of oral anticoagulation, most importantly older age, prior stroke, and cardiovascular comorbidity. In recent years, protein biomarkers, such as cardiac troponin, reflecting myocardial damage, and NT-proBNP (N-terminal pro-B-type natriuretic peptide), reflecting cardiac stress and dysfunction, have been shown to be more important for prediction of ischemic stroke than all clinical information, except prior stroke, in patients with AF. Biomarkers reflecting pathways of inflammation, renal function, coagulation, and platelet activity have also been investigated, although without consistent evidence of association with risk. To better understand the remaining risk of ischemic stroke in anticoagulated patients with AF, there is a need to further explore additional mechanisms. To explore the pathophysiological features of ischemic stroke in patients with atrial fibrillation (AF), the authors evaluated the association between 268 plasma proteins and subsequent ischemic stroke. The authors explored this new biomarker screening approach to identify plasma biomarkers associated with subsequent risk of ischemic stroke or systemic embolism (SE) and to improve the mechanistic understanding of ischemic stroke risk in patients with AF on oral anticoagulation (Hijazi Z, Wallentin L, Lindback J, *et al.* Screening of Multiple Biomarkers Associated With Ischemic Stroke in Atrial Fibrillation. *J Am Heart Assoc* 2020; 9: e018984).

EDITORIAL

THE UNFINISHED WAR - MICROORGANISMS AGAINST HUMANS SARS-CoV-2 - THE ENEMY FROM NOWHERE

Throughout history, humanity was confronted with many epidemics which were generated by different types of microorganisms: parasites, bacteria or viruses. However, in the last two centuries the fight against these invisible enemies has advanced through the implementation of antiseptic measures, vaccines or different medicines (especially antibiotics). In the last hundred years only, a few epidemics were classified as pandemics: the Spanish flu - 1918-1920 (minimum 50 million deaths), the Asian flu - 1957-1959 (2 million deaths), the Hong Kong flu - 1968-1969 (2 million deaths), and HIV - in the last four decades (35 million deaths) (1).

At the end of 2019 a few cases of a particular form of pneumonia with an unknown origin were discovered in Wuhan city in China. The presumption of a viral origin in these cases was confirmed by the identification of a new form of a coronavirus, named SARS-CoV-2. This virus presents a high virulence and is characterized by a rapid spread from those infected to the healthy population. For these reasons, at the beginning of 2020 World Health Organization (WHO) declared SARS-CoV-2 infection a public health emergency and three months later this epidemic was classed as a pandemic. In the last two years, the cases of COVID-19 spread around the world, approximately 219 million people became infected, and 4.54 million individuals died (2).

The big question is why the epidemic spreads so quickly and why the infection is so virulent? The answers are difficult to find, but certainly the particularities of the virus are intricate with some features of the host.

Coronavirus represents a class of viruses found in animals and humans, but its implication in human pathology has been limited, the first report of a disease caused by a coronavirus was in 1965 and only seven Coronavirus strains were associated with human pathology. Three of these viruses determined epidemics: SARS, MERS and COVID-19. In all three cases the viral reservoir is represented by different types of bats and the transmission from bat to human implied intermediate hosts: palm civet (SARS) dromedary camels (MERS) and minks and pangolins (COVID-19) (3-6).

Coronavirus belongs to the *Coronaviridae* family of the *Nidovirales* order, *Orthocoronavirinae* subfamily, *Sarbecovirus* subgenus and genus beta *Coronavirus*. The microscopic aspect of this virus is a spiked sphere, a shape that allows attachment to host cells. The genome of Coronavirus is an RNA type, and its' multiplication requests the use of translation machinery of the host. By this way, the host cells allow the multiplication of Coronavirus and production of many viral entities able to infect other cells, but also to spread to other people. The genome of COVID-19 is big for a viral genome and contains around 30 kilobases. Some genes of this genome codify structural proteins (essential for formation of virus - spike [S], envelope [E], membrane [M] and nucleocapsid [N]) while others - open reading frames of the

replicase complex (orf1ab) - codify different proteins and enzymes necessary for the multiplication of the viral genome or intermediate interactions virus-host, by modulation of production of pro-inflammatory cytokines. The dimension of the viral genome offers a large base for the accumulation of new mutations, and also its recombination is very important (6-8).

The pathogenic mechanism of SARS-CoV-2 is complex and implies a linked connexion between virus and host. Fixation of the virus by spike protein at host cell is allowed by the membrane receptor for ACE2 (angiotensin converting enzyme 2) but this process depends on the presence of serine protease TMPRSS which acts as primer for viral protein S. Since some human tissues like the lungs, kidneys, liver, intestines, heart and T lymphocytes have a high number of ACE2 receptors on cell membrane, these tissues represent the most important way for SARS-CoV-2 to enter (7, 8).

After the release of the viral genome in the host cell cytoplasm, translation and replication begins. Firstly, the viral non-structural proteins are synthetized by translation. These proteins are involved in a discontinued transcription of viral RNA, by which new RNA strands are produced, and also is produced the synthesis of structural proteins: S, E, M and N. The nucleocapsid incorporates viral RNA and is joined together with S, E and M into the membrane of the endoplasmic reticulum. After the complete viral structure is formed, Coronavirus passes into the Golgi vesicle. At the end of the process, the mature virus is released into the extracellular environment by exocytosis (1).

Another challenge in the fight against SARS-CoV-2 is the polymorphic symptomatology that ranges from cases with minimally ill patients to complicated cases that require intensive care and respiratory ventilation (9, 10). The frequency of asymptomatic infections is yet to be determined and the differentiation between those and pre-symptomatic cases should be considered (9, 11). In contrast with other infections with Coronavirus when fatality rate was high, infection with SARS-CoV-2 is characterized by an overall fatality rate of 2.3%. Despite this low rate of fatality some groups of patients present a very high rate of fatality: 14.8% in older patients (aged over 80) or 49-61% for individuals that required ventilator support in intensive care unit (9). The most important risk factors are old age, arterial hypertension, diabetes mellitus, obesity, cardiovascular, pulmonary, and cerebrovascular pre-existing diseases (12). The onset of COVID-19 is insidious, with non-specific signs and symptoms of upper airway viral infection (fever, fatigue, cough, and dyspnea, anorexia, myalgia, and productive sputum), which evolves to a particular form of pneumonia, sometimes complicated with acute respiratory distress syndrome that requests mechanical ventilation or extracorporeal membrane oxygenation. In other cases, a gastrointestinal symptomatology was described, with nausea, vomiting, and diarrhea (9, 13, 14). This particular pattern of symptomatology is probably correlated with the presence of a high number of ACE2 receptor in the epithelium of respiratory and gastrointestinal tracts.

Many patients with COVID-19 present a neurological symptomatology that ranges from anosmia and dysgeusia in less severe cases, to meningitis, encephalitis, myelitis, and Guillain-Barre syndrome as components of severe COVID-19. Even, respiratory failure could present a neurogenic part (by viral invasion of the respiratory cen-

ters) added to local modifications of the lungs (15). Another particularity is a tendency for coagulopathy, thrombosis, microthrombosis, and even a disseminated intravascular coagulation during severe COVID-19 (16). This coagulopathy could be accompanied by septic shock and metabolic acidosis. Coagulation issues are associated with an excessive inflammation and a cytokine storm triggered by the presence of the virus in the body and an inhibition of the adaptive immune response by reducing the IFN-γ secretion. All these allow a high rate of fatality, especially in elderly patients and those with underlying disorders (9, 17, 18).

Pediatric symptomatology of COVID-19 is usually extremely low, but some children have presented a severe clinical picture with auto-inflammation and vasculitis, similar to Kawasaki disease. The low severity of disease in childhood could be linked to innate immunity (intermediate by IFN-γ secretion) that slows down the viral infection before the adaptive immune response (9, 18, 19).

The differences in the hosts' response to the aggression of SARS-CoV-2 infection derive from genetic polymorphisms of the human beings. Such variations concern different genes, but the most important are genes involved in the immune defense system (MHC/HLA or CCR5) and those that allow the virus to enter the human cells (gene for *ACE2* or genes for *TMPRSS2* and lysosomal cathepsins). For example, the expression of ACE 2 proteins in human cells is higher in Asian males than females (especially in lungs) and this is correlated with a high degree of severity of COVID-19 (20). On the other hand, the expressions of *ACE 2* gene and also of *TMPRSS2* gene in nasal and lung epithelial cells are low in children and this explained partially the reduced severity of COVID-19 disease in this population group (8). The polymorphism p.Arg514-Gly of the *ACE2* gene is associated with severe cardiovascular and pulmonary complications in the African or African American population with COVID-19 disease (21). Individuals with blood type A are more vulnerable to SARS-CoV-2 compared to those with type blood O (22). The HLA polymorphisms are also important in the COVID-19 disease: HLA B*46:01 confers vulnerability to disease while HLA B*15:03 generates protection (23). Another genetic polymorphism is located 3q21.31, when there is a cluster of six genes (*SLC6A20*, *LZTFL1*, *CCR9*, *FYCO1*, *CXCR6*, and *XCR1*), derived from the Neanderthal genome. The polymorphism rs11385942-GA of this region is associated with severe disease and respiratory failure and its frequency is high in modern populations that conserve part of the Neanderthal genome (especially the Asian population) (24). Other genetic polymorphisms were described in the *ApoE*, *IFITM3*, *TLR7* and *TMEM189- UBE2V1* genes (25).

On the other hand, females, especially during their reproductive years, are more resistant to infections than men, a feature mediated mainly by estrogen. However, the differences between men and women could be explained by some environmental factors, like higher levels of smoking and drinking among men compared to women or the more responsible attitude of women toward the COVID-19 pandemic than men (20).

The confirmation of the SARS-CoV-2 presence in patients with COVID-19 imposes the use of different molecular methods like rapid diagnostic tests, real time - polymerase chain reaction (RT-PCR) multiplexes respiratory virus infection assays,

clustered, regularly interspaced short palindromic repeats (CRISPR), and metagenomics next gene sequencing (mNGS). By using such techniques, a final result is obtained in maximum one day. The RT-PCR test has become the standard method for diagnosis of this infection, and it targeted different sequences of the COVID-19 genome (orf1ab, S, E, M and N genes). However, RT-PCR has many limitations, the most important being the false-negative rates linked to high genetic diversity of viral genome. In cases with negative results of RT-PCR tests, it is useful to apply shotgun mNGS including short-read and long-read sequencing. Also, CRISPR or electron microscope technology could offer an early diagnosis, but its routine use is not yet applicable (26, 27).

The onset of epidemics with COVID-19 finds humanity without any therapy or vaccine against SARS-CoV-2. In these conditions, a variety of approaches was triggered in order to design and develop a novel drug and/or vaccine. Searches of a useful treatment were directed to the application of existing broad-spectrum antiviral drugs, screening of libraries that contain existing chemical compounds and the redevelopment of new specific drugs based on the genome of coronaviruses. The most promising therapeutic approaches were viral receptor blockers, monoclonal antibodies or gene silencing. Antibodies against the receptor-binding domain of the spike protein or antibodies that bind to the ACE2 receptor represent potential therapies. Monoclonal antibodies against the spike protein allow the block of virus attachment, fusion, and entry to the host cells. An immunotherapy that uses plasma from convalescent COVID-19 patients has also been used (8, 28, 29).

In addition, different strategies were applied to develop a vaccine: epitope-based peptide vaccines, viral vector-based vaccines and use of bioinformatics and immunoinformatics to design more efficient targets. More than 300 vaccines for COVID-19 are being developed, and many of these have already passed the clinical trial phase. The most revolutionary approach was the development of "genetic" vaccines, based on genetic engineering that use some part of SARS-CoV-2 genome (especially S gene) or allow a synthetic defective mRNA from SARS-CoV-2 to trigger immune response. Such mRNA vaccines have a low risk of integrating into the host's genome and thus present a high advantage reported to other type of vaccines. Worldwide, the development of vaccines for COVID-19 was very quick, and this particularity can be correlated with the existence of previous knowledge about the pathogenic mechanism of Coronavirus (obtained from studies conducted during previous epidemics with SARS and MERS) and with record-breaking speed which the SARS-CoV-2 genome was sequenced with (25, 28-30).

The last two years have brought many successes in the battle against SARS-CoV-2, but many questions remain unanswered. Some features like the differences of severity in different population groups (children vs. elderly; men vs. women), the wide range of severity from asymptomatic people to the seriously ill in individuals without associated conditions, the ethnic differences of severity, the presence of individuals with a long period of RT-PCR positive values, people who develop a tiny immunity after disease, the differences in response to therapy or vaccine and also the differences in recovery after COVID-19, have only partial explanations. Some answers were provided by studies of genetic polymorphisms, but

deciphering the full enigma requires further research on the viral and human genomes and interactions between these two genomes. In addition, past mistakes should not be repeated, such as stopping research on Coronavirus in SARS and MERS epidemics, which prevented the development of high-performance vaccines. We will probably have to live with COVID-19, and the best protection option will be the regular application of active vaccine variants against the new virus strains.

EDITORIAL

THE MEDICAL-SURGICAL JOURNAL OF THE SOCIETY OF PHYSICIANS AND NATURALISTS OF IASI ON THE ANNIVERSARY OF 125 YEARS OF PUBLICATION AND 135 YEARS SINCE ITS FOUNDATION

The Society of Physicians and Naturalists of Iași and its first periodicals

The Society of Physicians and Naturalists of Iași. Established on January 11, 1830, as "The Iasi Circle of Medical Reading" (*Jassyer medizinische Leseverein*), the Society of Physicians and Naturalists of Iasi (SPN) was due to the initiative of Dr. Iacob Cihac and Dr. Mihail Zotta, supported by both by the Doctoral Council (Doctoral Commission) structured in 1829 in the capital of Moldavia, as well as by representatives of the political parties and progressive intellectuals. It was soon transformed into an academic society. Indeed, in the spirit of the Organic Regulations (Organic Laws), on March 18, 1833, the Government of Moldavia approves the creation of the "Society of Physicians and Naturalists of the Principality of Moldavia" (SPN). It was the first scientific association in the Romanian Lands and in South-East Europe. Besides the specific goals related to the development of medicine and pharmacy, health care and health education of the population, SPN promoted national emancipation through culture, political union of the Romanian Countries and cooperation between the Romanians from everywhere, but it also encouraged the use of the Romanian language, which was adopted by all the publications of this association. From the very beginning, the Society had a well-defined European personality and its work largely consolidated European scientific spirit in Moldavia and Romania.

1844-1845. The Advisor of Health and Economy. In this context, under Dr. Costache Vârnav's editorship, the *"The Advisor of Health and Economy. Periodical Leaflet for the Romanian People" (Povățuitorul sănătății și a economiei. Foaie periodică pentru poporul românesc)* was printed in Iași on March 1, 1844. It was the first medical popularization journal in Romanian, a real landmark in this field as Dr. Victor Gomoiu specified. Published between 1844-1845 under the SPN auspices, "The Advisor" dealt with the state of rural hygiene and economy in this corner of the world. The motto of the "Periodical Leaflet for the Romanian People" was: "To keep one's health and to spare one's wealth is the effort of a wise man." Due to his tenacity to impose this medical-sanitary, economic and veterinary periodical, Dr. Vârnav contributed to the formation, improvement and dissemination of Romanian medical terminology, to the popularization of general data on human and veterinary domestic medicine and the spread of the home economy in the Principality. In 1848, according to some authors, the "Medical-historical-natural and agronomic gazette" was to be printed in the Moldavian capital, but it probably remained a mere and ephemeral attempt, or just a simple intention.

1851-1853. The Leaflet of the Society of Physicians and Naturalists of the Principality of Moldavia. After many "projects and prospectuses", the perseverance to create a high standard scientific journal of the SPN, whose activity to be reflected in detail, materialized by the appearance, between July 1, 1851, and June 1, 1853, of

the weekly "Leaflet of the Society of Physicians and Naturalists of the Principality of Moldovia" (*Foaia Societăţii de Medici şi Naturalişti din Principatul Moldovei*). It was the first periodical in Romanian edited by a national scientific association, a landmark in the history of the Romanian medical press, as Dr. Victor Gomoiu mentioned in his iatro-historical writings (1). With great effort, the edition was coordinated by the same dedicated Dr. Costache Vârnav, in charge of this responsibility by Dr. Gheorghe Cuciureanu (Cuciuran), SPN President in office. Among the constant collaborators of the periodical there was a skilled physician, pharmacist and botanist, Dr. Josif Szabó, able to distinguish, classify and describe the medicinal plants of the Moldavian flora. A note of the Editorial Board in the first issue let readers know that the publication was going to include "articles on natural sciences, and especially folk and domestic medicine, dietetics, hygiene, veterinary medicine, and home economy." In addition, *"The Leaflet"* was equally concerned with agriculture in terms of soil maintenance and promotion of new vegetables, especially maize and potatoes, without overlooking domestic business and trade (1, 2). Details about the SPN activity and members were published as well.

A "serious, competent and useful" periodical of the Society

1887. The Bulletin of the Society of Physicians and Naturalists of Iasi. In 1885 *"The Medical Newspaper of Iaşi"* (*Gazeta Medicală din Iaşi*) was edited in the Moldavian capital of culture and science by Professor Dr. Vasile Bejan, as its director. Always overcoming the vicissitudes of times and the opposition or indifference of the people, on March 21st, 1868, Dr. Gheorghe Iuliano, an experimented dermatologist, and the famous geologist Professor Dr. Grigore Cobălcescu outlined once more the need for a periodical of the Society. On April 24, 1874, the proposal was reformulated by the SPN president, Professor Dr. Anastasie Fătu. Equally commendable was the resumption of work in 1876, at the insistence of the same Prof. Dr. Cobălcescu, supported by Dr. Aristide Peride, professor of anatomy and embryology, and several other members of the Society. A periodical entitled "The SPN Archives", a high-level scientific journal, was intended to be edited. But it was not until November 28, 1886, that "after long debates and incessant obstacles", under the chairmanship of Professor dr. Ioan Ciurea outstanding SPN members made the firm decision to publish a "serious, competent and useful" periodical of the SPN. This resolution was adopted by Dr. Ioan Ciurea, professor of forensic medicine, SPN President, following the proposal reiterated by Prof. dr. Peride, convincingly supported by the Academician Cobălcescu, notable professor of geology, together with Dr. Gustav Otremba, chief doctor of the Army in Iași, Dr. Eugen Rizu, professor of *Materia medica and the Art of formulation*, and with the help of many enlightened SPN members among the "most distinguished professors of the Iași Faculty of Medicine".(3) On January 1, 1887, the first issue of the "Bulletin of the Society of Physicians and Naturalists of Iasi" was printed, under Professor dr. George Bogdan's Presidency of the Society of Physicians and Naturalists of Iași. Dr. Peride, Prof. Dr. Cobălcescu, Dr. Otremba, Dr. Rizu, Dr. Bottez and Dr. Konya formed the first Editorial Board. It was a monthly *Bulletin*.

From 1888 to 1900, the publication appeared under Prof. dr. Bogdan's successful direction (2).

1887-1924: The first period of the Bulletin. Initially, the content of the *Bulletin* encompassed more domains, like e.g., natural sciences, geology and philosophy. Romanian and French became its official languages. Not only forging an enriched Romanian scientific vocabulary was targeted, but integration, communication and exchanges with the international medical and scientific communities were envisaged as well. It was only in January 1887 that the legacy of Costache Vârnav and his generation was dimensioned by the publication of this new journal, "able to determine a beneficial movement". After a short period of calm or "languor" from 1860 to 1885, the Society entered an "era of regeneration" with the publication of its scientific *Bulletin* (2, 3). *The SPN Bulletin* appeared with remarkable regularity and information from it were reported in foreign journals, as SPN President, Dr. Otremba, noted with satisfaction in 1890: "We started with scarce, very modest means, I have no doubt that we will make progress - and we will show our descendants the path they must follow" (4). The first four issues were sent to Dr. Iacob Cihac at Aschaffenburg, and, in a warm letter to the Society of Physicians and Naturalists he had founded in Iasi, he immediately expressed his joy and satisfaction that his dream could finally come true. Cihac specified that he intended to communicate this good news to foreign Societies of Natural History in order the relationships with them to be resumed (2).

From its very beginning, *The SPN Bulletin* was exchanged with many other national and international publications. The Society of Physicians and Naturalists thought it was "far from fulfilling its purpose if the published works could not be known and controlled by the whole scientific world" (4).

This viable SPN periodical could only appear almost a decade after the Faculty of Medicine in Iași was inaugurated in 1879, when a more professional medical stuff got involved in this work, and when both the number of scholars and the scientific and cultural level of the intellectuals in Iași greatly increased due to the existence of the first modern University of the country, established there in 1860. This aspect was already mentioned in the *Foreword* of the first issue of the *Bulletin*: "To the Readers" – this publication and "the proliferation of scientists and scientific societies" occurred also "thanks to the progressive development of the Faculties of Science and of Medicine - which, although recently established and in its infancy, still has a focus on scientific activity".

In 1897, the *Bulletin* was printed only in Romanian, but it continued to be viable, even when exclusively the Romanian language was used, a fact that obviously restricted its international access. Paradoxically, a Society with only 49 "ordinary members" in 1896, managed to support a valuable *Bulletin*, the proof being, among other things, the fact that no less than 92 scientific journals were received in exchange from abroad (2). Among the close collaborators of the *Bulletin* there were famous Romanian scientists of Iași, such as Grigore Cobălcescu, Leon Cosmovici, Samuel Konya, Nicolae Leon, Leon Papp, Emanuil Riegler, Gabriel Socor, Ludovic Russ junior, Vasile Negel, Theodosie Philippescu, Constantin Bottez, Theodor Bastaki, Victor Imervol, Constantin Thiron, or the philosopher Vasile Conta. From Bucharest, e.g., Zaharia Petrescu and Alexandru Șaabner-Tuduri had their research published in the *"Iași SPN Bulletin"*.

With sacrifices and efforts, the Society's periodical was published in its first form, from 1887 to 1912, when it was re-

named *"Bulletins et mémoires de la Société des Médecins et des Naturalistes de Jassy".* The 58th and 75th anniversaries of the SPN foundation in the fall of 1890 and in 1909/1911, respectively, were accompanied by jubilee editions of the *Bulletin*. The content of this scientific tribune of the Iași Medical-Naturalist Society included summaries of SPN manifestations, annual administrative and scientific reports, minutes of meetings, original communications with a wide range of topics, reports and reviews on papers or communications published in other journals and up-to-date scientific topics under debate in the country and abroad, meteorological tables for Iași.

1912-1923. Although in its first decades, SPN lived in the aura of the German culture due to the decisive influence of Dr. Iacob Cihac and other German-speaking graduates from foreign educational institutions, and, after 1866, due to the new wave of German-speaking Romanian intellectuals, the Society added on the shelves of its Library a dominant number of French language books and journals.

Works by French scholars were also offered to the *Society* for reviews to be printed in its *Bulletin*.

On the eve of the First World War, SPN received a large number of journals donated or sent in exchange for "our modest Bulletin", as Dr. Gustav Otremba put it. Francophone literature obviously predominate (2, 3). The periodicals exchanged with the *SPN Bulletin* came from Bucharest, Iași and abroad: France, Germany, Switzerland, Italy, Belgium, Russia, USA, Spain, Portugal, Greece, Poland, Vienna and Prague (Austro-Hungarian Empire), the Netherlands, Turkey, Uruguay, Brazil, Argentina.

Between 1912 and 1923 the name of the SPN periodical was changed to *"Bulletins et Mémoires de la Société des Médecins et des Naturalistes de Jassy",* being edited both in French and Romanian.

The publication of the *Bulletin* ceased in 1916, during World War I, when only four issues appeared, and it was resumed some years later, in 1923, with the cumulative volume XXXI.

Prominent professors and physicians of the Iași Faculty of Medicine were members of the Editorial Board and authors of papers: Alexandru Brăescu, Panait Zosin, Gheorghe Demetriade, Constantin Bacaloglu, Constantin I. Parhon, Paul Anghel, Alexandru Tzaicu, Mihai Ciucă, Alexandru Slătineanu, Elena Pușcariu, Mihai Manicatide, Gheorghe Tudoranu, Vladimir Bușureanu, Gheorghe Plăcințeanu, Nicolae Hortolomei, Emil Hurmuzachi, Alexandru Moruzi, Corneliu Șumuleanu, Leon Ballif, Ion Bălteanu, Ion Alexa, Dumitru Brănișteanu, among many others (5).

1924-1949: The second period of "The Medical-Surgical Journal of Iași". From January 1, 1924, Dr. Răşcanu, SPN President in office and professor of Physiology, modified again the publication title in order to point out its exclusive medical character. Hence its 35th volume became *"The Medical-Surgical Journal of Iași. Bulletin of the Society of Physicians and Naturalists".* The title was expressed either in French - *"Revue Médico-Chirurgicale. Bulletin de la Société des Médecins et des Naturalistes de Jassy*" - or in Romanian: *"Revista Medico-Chirurgicală din Iași. Buletin al Societății de Medici și Naturaliști".* It was published every two months, i.e., each volume comprised six issues per year, summing up about 600 pages (6). Its subtitle – *SPN Bulletin* – reminded the tradition and continuity of the original denomination: *"Bulletin of the Society of Physicians and Naturalists of Iasi".* The volume XXXV, the first of the new series,

had 44 pages, signed by outstanding specialists who remained in the history of the Iași Faculty of Medicine and of Romanian medicine, like, e.g, Gheorghe Tudoranu, Vladimir Bușureanu and Gheorghe Plăcințeanu.

Interesting clinical, medical-surgical and laboratory studies, original articles, meteorological tables, biostatistical and epidemiological assessments regarding especially Moldavia, inaugural lectures, commemorations and obituaries were published, together with summary presentations of both SPN activities, along with reports on different manifestations in the country and abroad. Papers from foreign contributors, book and article reviews published around the world were integrated, too. The *Journal* also consisted of book and article reviews, minutes of the SPN meetings, and popularization of various aspects concerning the medical life of Iași. This was a period of consolidation and high productivity of the *Journal* and evolution of modern medicine during those years was reflected.

In the interwar and post-war decades**,** from 1924 to 1949, *The Bulletin* ..., respectively *The Medical-Surgical Journal* ... greatly improved its quality, the topics being deeply rooted in the regional and national everyday medical practice and theory, and concurrently synchronized to international events and discoveries. International congresses, mainly held in France, were announced in *"The Medical-Surgical Journal".* This editorial policy maintained the European profile of the publication.

The specialized scientific Romanian vocabulary was substantially enriched and acquired an increasingly natural allure.

The SPN Bulletin continued to be exchanged with foreign journals. In 1929, for example, out of the 500 copies of the *Bulletin*, 63 were sent abroad, and 34 periodicals were received. In 1931, old numbers of the *Bulletin* were requested by the British Museum to complete its collection. In 1932, *"The Medical-Surgical Journal"* was considered by the Hygiene Department of the League of Nations in Geneva to be one of the "great medical publications" (4).

The SPN *Bulletin* was still printed during the Second World War, under the title of "*Revue Médico-Chirurgicale. Bulletin de la Société des Médecins et des Naturalistes de Jassy*" or *"Revista Medico-Chirurgicală din Iași. Buletinul Societății de Medici și Naturaliști".*

But "1944-1945 was a difficult time for Iași, which lost its usual intellectual turmoil, to become a theater of territorial and corporal turmoil. Our war-torn society suffered severe damage. The printed material for the last issues of 1943 was destroyed before being handed over. The headquarters of the Society were hit by 11 bombs, 4 of which directly affected the building, partially demolishing it and destroying a large part of the collections gathered and arranged there with great effort (...). And yet, after this material turmoil, its ruins and the time of a totally new spiritual and social turmoil, we dare to concentrate our strength again and reappear. (...) We hope for peace and good times"- the editors confessed in the *Foreword* to volume 57, no.1, 1946.

Apart from topics related to war surgery or the onset of epidemic diseases, the content did not betray the tragedy of the moment. In the pages of the *Journal* there were articles related to medical research and practical experience, synthetic reports, inaugural lectures of great professors, deontological approaches belonging to Iași and other Romanian medical and pharmaceutical centers (4).

For a while, after 1948, the interde-

pendence between the SPN, its *Journal* and the Faculty of Medicine was clearly stated on the publication cover, where it was specified: "*Published under the scientific direction of the teaching staff of the Faculty of Medicine*".

1949-2012: The third period of "The Medical-Surgical Journal of Iași" went through several stages including its suppression and rebirth. Between 1943 and 1946, years of the Second World War, the SPN postponed its meetings. The newly established communist government was obsessed with centralizing the press and controlling information. In 1949, for political reasons *The Medical-Surgical Journal*… ceased to appear. After 1949, under the constraint of the radical changes that took place in post-war Romania, including its scientific life, both the SPN and its publication were in danger of being prohibited or losing their identity. Eventually the SPN became the local section of the unique Romanian Society of Medical Sciences (SSM) based in Bucharest, whereas its *Bulletin* was suppressed. However, through the energetic intervention of some personalities of both the Faculty of Medicine of Iași and SPN members, among which Acad. Prof. Dr. Vasile Rășcanu, efficiently supported by Acad. Prof. Dr. Constantin I. Parhon and Acad. Prof. Dr. Nicolae Hortolomei, former famous professors of the Iași medical school and presidents of this academic Society, the SPN was able to keep not only its name, but its publication, too, even after it became the Iasi Branch of the Medical Sciences Society in Romania (SSM) (6). Founded in June 1949 in the country's Capital, the SSM was transformed into the Union of the Medical Sciences Societies in Romania (USSM) in 1962.

On April 27th, 1950, it was stated that the Iași Branch of the SSM represented the continuation of the Society of Physicians and Naturalists created in 1830. Consequently, it was renamed: *"The Society of Physicians and Naturalists. The Iași Branch of the Medical Sciences Society".* The problem of restoring the former title of the SSM Branch in Iași and the resumption of the publication of the *Medical-Surgical Journal* were re-discussed during the debates on the SSM Statute in September 1955, when the SSM was organized into sections. On that occasion, the SPN - The Iași Branch of the SSM also proposed medical periodicals to be expanded, allowing all SSM Branches existing in the university centers of the country to edit specialty journals, because the suppression of such local-regional *Societies* and Journals in 1949 had significantly restricted the scope, dissemination and valorization of research activities (6). The pleadings were won on June 21, 1956, when a festive plenary session was held. Finally, the *Medical-Surgical Journal* reappeared as an organ of the SPN, the Iași SSM Branch.

Consequently, interrupted in 1949, the publication of the *Medical-Surgical Journal* was restarted six years later, in 1956, when its 60th volume was edited. Acad. Professor Dr. Vasile Rășcanu, "the second founder of the Society" (i.e., after Cihac), was the editor in chief of the *Journal* and SPN President (1956-1973). The editorial signed by Acad. Professor Dr. V. Rășcanu and entitled "The historical and scientific significance of the Medical-Surgical Journal of Iași" was a plea for the continuity of the periodical. The editorial board included Acad. dr. V. Rășcanu (editor-in-chief), Prof. Dr. Șerban Brăteanu and Prof. Dr. Vladimir Bușureanu (associate editors), Assoc. Prof. dr. Theodor Economu, Assoc. Professor Dr. Gheorghe Popovici and Professor Dr. Ernest Ungureanu (editorial

secretaries). Ten years after the resumption of the publication, 20 million pages had been printed and there were 2,000 subscribers.

In these post-war series from 1956 to 1989, the title of the publication was *"The Medical-Surgical Journal of the SPN of Iași, Branch of the SSM in the Romanian People's Republic*", and after 1965, "Medical-Surgical Journal" of the SPN of Iași, Branch of the USSM in the Socialist Republic of Romania. Meant to outline its long history and permanence, the previous versions of the SPN periodicals were illustrated on the cover page of the new edition: *"The Advisor of Health", "The SPN Leaflet"* and *"The SPN Bulletin".* As usual, covers II-III-IV mentioned the exchanges with foreign publications. Once again, the tradition of the longest-lived Romanian medical periodical was emphasized. The name of *"The SPN Medical-Surgical Journal"* has been preserved to this day.

Although the post-war language was exclusively Romanian until 1990, the articles were accompanied by abstracts in foreign languages: French, Russian, English or German. As customary, the *Journal* recorded research results, clinical cases, reviews and reports of the SPN activity usually written by representatives of the medical and pharmaceutical stuff in Iași and Moldavia. Contributions by foreign scientists achieved independently or in collaboration with Romanian colleagues were sometimes included, too. The *Journal* was offered in exchange for various publications from abroad, mostly European ones. It was an excellent and economic way to keep the SPN library updated in a period of extreme isolation and inadequate funding.

However, paradoxical as it may seem, from 1965 to 1989 "*The Medical-Surgical Journal"* and the SPN itself went through their most prolific years not only in terms of the number of articles published and of undertaken activities, but equally in terms of their scientific quality and variety of topics. The *Journal* turned into a real methodological forum. In 1975, Professor Dr. Grigore Teodorovici was elected editor-in-chief, and he proved to be one of the best directors ever of the SPN publication, which could benefit from his competence and editorial skills until the end of his life, in 1992. He towered over this third golden period of the *Journal*. His best collaborator was Professor Dr. Traian Mihăescu.

The centenary. *„The Medical-Surgical Journal",* volume 91, no.1, January-March 1987, only remembered the100th anniversary of the publication of the first issue of the *Bulletin of the Society of Physicians and Naturalists of Iasi* that had occurred on January 1, 1887. But, since in some years the *Bulletin* did not appear due to real difficulties, volume 100, marking a century of effective appearance, corresponded to the year 1996.

December 1989-2012. So, it was in 1996 that the centennial volume of the SPN periodical could be really celebrated. A hundred years after its appearance, *"The Medical-Surgical Journal"* was the best general medical periodical in the country, being exchanged with 275 journals from 43 countries, and indexed in 22 databases, the most prestigious of whom was PubMed.

However, after the revolutionary events of December 1989, a new period of "languor" followed by another period of "regeneration" occurred. Little by little the SPN got inside the penumbra, because of the scientists' need to communicate their own results in high-profile publications indexed in international databases, but also in publications acknowledged and well rated by the Higher Education National Council of

Scientific Research in Romania. This fact-maintained scholars' interest in *"The Medical-Surgical Journal of the SPN"* to a certain extent but at the same time urged the *Journal* to keep pace with changes and impelling demands of the day. The SPN periodical reconfirmed its role and achieved a remarkable and constant recovery in the last decades. Succeeding Professor Dr. Teodorovici, since 1992 editor-in-chief was Professor Dr. Valeriu Rusu, who fulfilled his duty with competent efficiency and dedication until his death. Articles, monographs, treatises of major publishers continued to be reviewed, the SPN Library being thus enriched.

The openness produced in the Romanian society and the diligence of the editorial boards soon rendered the *Journal* one of the most appreciated national publications the CNCSIS finally rated in the B+ category. The printing of contributions in international languages has intensified, and from 2012 on, all articles are published exclusively in English. In 2008, the number of pages for all the four issues was 1160 and there were 1000 subscribers.

2012 to nowadays: ***the fourth period of the Journal***. Considered by international databases, such as Index Medicus, Excerpta Medica, Medline and PubMed, *"The Medical-Surgical Journal"* has been monitored since March 3rd, 2011, for evaluation according to Thomson-Reuters / ISI criteria. Since the last issues in 2012, the Iași SPN periodical appeared exclusively in English.

On October 28, 2016, at the end of its 120th editorial year, *"The Medical-Surgical Journal"* has been indexed in the Thomson Reuters Web of Science (*Emerging Sources Citation Index-Journal List*) - current Clarivate - Analytics Web of Knowledge, even though no impact factor has been calculated for it as yet. A special merit for this turn belonged to Professor Dr. Aurel Ivan, who endeavored and succeeded to have this publication acknowledged by Clarivate - Analytics Web of Knowledge.

Due to Professor Dr. Aurel Ivan and his team *"The Medical - Surgical Journal"* maintained its format and cover, acquired a better editorial quality, and began to observe stricter rhythmicity of its issues. It has a national and international editorial board and publishes articles from Iași and other Romanian university centers, as well as from abroad.

The *Iași SPN Journal* continues to have the same generalist character as always, covering various fields: basic bio-medical sciences, surgical specialties, medical specialties, dental medicine, pharmacy and medical bioengineering. Since 2021, general reports, reviews and clinical cases have been abandoned.

The historical and scientific significance of the Medical-Surgical Journal of Iași. The Society of Physicians and Naturalists of Iași and its *Journal* went through two world wars, a communist dictatorship, suffered during transition, but survived, proving that *„the great works of humanity are done by people who manage to overcome the situational incapacities of the times"*- said Professor Dr. Gheorghe Scripcaru, one of the SPN Presidents. As always in its long history, now, once again, united forces are needed so that the soul of this Society and implicitly of its periodical remain vivid, so that its projects could still inspire vitality and find constant echo both in the Romanian and medical communities worldwide. Globalization and European integrative requirements of the 21st century have imposed the adoption of the English language for the *SPN Journal* to be available and accepted in the international circuit of values.

Time, facts and people, the stylistic matrix of the Romanian nation always had to make the right choices between complementary identities, embracing progress and multiculturalism. Consulting today *"The Medical-Surgical Journal"* collection, one of the few in the world that spanned over 100 years, gives us a glimpse into the long way the Romanian society travelled in order to get synchronized to universal scientific progress and welfare.

Concurrently it illustrates a reliable source of documentation that highlights the specificities of the medical school of Iași, its problems, glorious moments and brilliant personalities, important for Romania, but for science as a whole, as a transnational entity, too.

The close cooperation of the 191-year-old SPN with the 142-year-old Faculty of Medicine, and later with the Institute and then the University of Medicine and Pharmacy of Iași, along with the 264-year-old "Sf. Spiridon" Establishments, constituted the key point of their together evolution, resistance and adaptation in the achievement of social implementation of knowledge, medicalization of the society and professionalization of medical and pharmaceutical practitioners and researchers.

In 2021, on the occasion of its 125th anniversary, *"The Medical-Surgical Journal"* was awarded a Diploma during the "Editorial Harvest Days" Book Fair in Iași.

Evoking and honoring the 125-year-old *"The Medical-Surgical Journal of the Society of Physicians and Naturalists of Iași"* also means understanding the importance of this pioneering national publication for the Romanian scientists and the Romanian society, as a hole, as well as the necessity to continue, following in our most noteworthy predecessors' footsteps. It is in this capacity to adapt successfully to challenging circumstances without losing identity that lays the source of the perpetual renewal of our values.

The *Society of Physicians and Naturalists of Iași* and its long-lived *"The Medical-Surgical Journal"* are such admirable paradigms in the Romanian history of science.

EDITORIAL

POST-COVID-19 CARDIOPULMONARY REHABILITATION

For more than two years the entire activity of world healthcare systems carries on under the sign of COVID-19. Beyond the acute problem, SARS-CoV-2 infection frequently associates long-term persistent symptoms and complications. After COVID-19, the patients may develop persisting dysfunction of almost any organ, resulting in a very wide range of symptoms and signs. These result from both organic sequelae and various functional imbalances, mainly of respiratory and cardiovascular nature, but also involving other systems, from the central nervous system to the peripheral muscles. Several months after the infection, persistent dyspnea, muscle weakness, fatigue, sleep disturbances, depression and anxiety often persist (1). Long term COVID-19 sequelae and complications are more commonly observed in patients older than 65 years, frequently associating cardiovascular diseases, diabetes or other chronic comorbidities. However, the consequences of COVID-19 are highly severe, even in young patients, if they require disease management in the Intensive Care Unit (ICU), for complications such as respiratory distress syndrome (ARDS) or multiple organ failure (2).

In the context of the epidemiologic implications and of the therapeutic particularities, including oxygen therapy and ventilation, COVID-19 patients remain bedridden for long periods, thus leading to muscle strength and mass reduction, increased risk of deep vein thrombosis and to an altered capacity of sputum clearance (3). Extended immobilization in ICU patients also determines more important complications such as neuromuscular complications, severe peripheral muscular weakness and fatigue, dysphagia, even quadriparesis, resulting in a significant quality of life alteration (2, 4). In addition, psychological problems, cognitive and emotional complications are common in COVID-19 patients, treated in ICUs (5).

RESPIRATORY SEQUELAE AND REHABILITATION RECOMMENDATIONS

Clinical evidence resulting from the limited COVID-19 experience, but also from previous outbreaks of Coronavirus resulting in Severe Acute Respiratory Syndrome (SARS), showed long term exercise capacity reduction, in the context of persistent pulmonary function impairment: restrictive ventilatory pattern, altered diffusing capacity in the alveolar capillary membrane, respiratory muscles dysfunction (6, 7). In addition, cardiorespiratory and musculoskeletal performance impairment determines an important quality of life alteration, after COVID-19 (8).

Pulmonary rehabilitation is a multidisciplinary personalized intervention, providing comprehensive care, in order to improve both the physical and psychological condition of patients with respiratory diseases (9). Pulmonary rehabilitation is based, but not limited to exercise training, including also psychosocial support, and measures of education and behavioral mod-

ification. Pulmonary rehabilitation increases the functional capacity, reduces symptoms as dyspnea and improves quality of life, even in patients with irreversible organic abnormalities of the lung. Although there are not enough studies regarding the benefits of pulmonary rehabilitation in post-COVID-19 patients, this intervention should be considered, as these patients may present some degree of functional limitation, partially due to the respiratory dysfunction (8).

The Stanford Hall consensus statement for post-COVID-19 rehabilitation, recommends as low intensity exercise (≤ 3 Metabolic Equivalents, METs) to be considered initially, particularly for patients who required oxygen therapy. Exercise training should be performed under the careful monitoring of vital signs and parameters (pulse oximetry, heart rate and blood pressure). Exercise intensity should be gradually increased, based on symptoms and perceived exertion (8). Aerobic exercise training such as walking, jogging, swimming is recommended 3 to 5 times per week, for 20 to 30 minutes each session. Intermittent exercise can be used in patients with a lower exercise capacity. Breathing training is recommended in patients with dyspnea, wheezing, difficult sputum discharge. This training should include breathing rhythm adjustment and breathing muscle group mobilization. Sputum training should aim to diminish sputum production and to reduce energy consumption with coughing. Some patients may need to be assisted through positive expiratory pressure or oscillatory techniques. Strength training may also be associated to aerobic training, by progressive resistance training, 2 to 3 times per week, for a 6-week period (2).

A comprehensive clinical and functional assessment should be done, before initiating the respiratory rehabilitation program, in order to conduct exercise training in safe conditions. Physical examination will be followed by lung imaging and laboratory testing, including inflammatory markers. Respiratory functional assessment includes spirometry, respiratory muscle strength measurement, diffusing capacity of the lung for carbon monoxide (DLCO) testing. Aerobic exercise capacity should be assessed by exercise testing, preferably by cardiopulmonary exercise testing. This allows a rigorous individualized determination of the workload level for aerobic exercise training, resulting in minimizing the risk and maximizing the benefits of physical activity (9).

In post-COVID-19 patients, respiratory rehabilitation has important benefits in relieving symptoms of dyspnea and cough and reducing anxiety and depression, resulting in significant quality of life improvements and in long term complications prevention.

CARDIOVASCULAR SEQUELAE AND REHABILITATION RECOMMENDATIONS

Cardiac complications and sequelae should be considered in all post-COVID-19 patients, regardless of severity. Most common cardiac complications of COVID-19 are arrhythmias and myocardial injury, determined by multifactorial mechanisms, i.e., like systemic inflammation, direct viral myocardial injury, hypoxia, or even drug toxicity (10). Advanced age, prior cardiovascular comorbidities and diabetes mellitus are important risk factors for cardiac complications (11). All post-COVID-19 patients should undergo an assessment of cardiovascular symptoms and some basic

or more advanced investigations may be necessary: ECG, 24-hour HOLTER ECG monitoring, echocardiogram, cardiopulmonary exercise testing, serum biomarkers of myocardial injury, cardiac magnetic resonance imaging (MRI). In case of post-COVID-19 myocarditis, a period of rest for some weeks, depending on symptoms and severity, will reduce the risk of heart failure (8).

Cardiac rehabilitation represents a priority for patients with prior cardiac pathology such as heart failure, myocardial infarction, coronary revascularization (12). The cardiac rehabilitation program should be individualized depending on the main cardiovascular pathology and cardiac complications of COVID-19. As in respiratory rehabilitation, aerobic exercise training represents the core component of the cardiac rehabilitation program. Exercise testing represents the best modality of prescribing the individualized workload level of the exercise. In addition to exercise training, management of cardiovascular risk factors, health behavioral change and education are other essential components of the cardiovascular rehabilitation programs (13). Current international guidelines show the benefits of cardiac rehabilitation not only by relief of cardiac symptoms, increased exercise capacity and improved quality of life, but also by reducing cardiovascular mortality and hospitalizations (12, 13).

MULTIDISCIPLINARY ASPECTS IN POST-COVID-19 REHABILITATION

Cardiopulmonary post-COVID-19 rehabilitation programs should be initiated in a hospital setting, as supervised interventions, especially for patients treated in ICU and for patients requiring oxygen therapy. However, after a comprehensive clinical assessment, rehabilitation can be continued as outpatient or even home-based programs. An important issue is the timing of initiating the rehabilitation of COVID-19 patients. There are some evidences that early bedside rehabilitation facilitates long term recovery reduces the duration of hospitalization and the time of assisted ventilation, in patients with important respiratory disease (4). On the contrary, there are situations when early respiratory rehabilitation is not well tolerated because it may determine significant rapid desaturation. For this reason, it is important to adapt the timing for initiating rehabilitation, depending on the individual response of the patient (2). Classically, an inpatient pulmonary rehabilitation program lasts between 6 and 9 weeks. However, there are not clinical studies on the post-COVID-19 period regarding the optimal duration of rehabilitation (14).

Clinical experience of the acute phase COVID-19 showed a high incidence of other medical consequences (hepatic, hematological, renal, gastrointestinal, endocrine), beyond those involving the lung and heart, as a direct result of the infection as well as an indirect result of medical interventions. It is unclear whether and which of these persist as long-term complications of COVID-19. However, post-COVID-19 rehabilitation should not ignore the multiorgan involvement. In this perspective, post-COVID-19 rehabilitation becomes a multidisciplinary patient-centered intervention, tailored to individual COVID-19 complications, as well as to individual comorbidities, needs and preferences of the patient.

A large number of patients with COVID-19 require ICU treatment, often

lasting for several weeks. Some of these patients developed a combination of physical, cognitive and psychological issues, defining "the post-intensive care syndrome": dyspnea, depression, anxiety, impaired exercise capacity, pain and altered quality of life (15, 16). Patients that have long ICU hospitalizations, frequently experience intensive care acquired weakness, resulting from rapid muscle mass loss. This worsens in case of multi-organ failure. Physical weakness may also occur in patients not admitted to ICU, in the context of deconditioning, which appears particularly in frail patients. These patients are more likely to require support by rehabilitation after the COVID-19 hospitalization (17).

Prone positioning for many hours per day represents an important measure for respiratory failure associated with COVID-19, in both ventilated and non-ventilated patients. This position determines an increased risk of compression neuropathies and peripheral neural damage. Neuromuscular blockades in orotracheal intubated patients may increase peripheral neural damage. Neuropathies and muscle atrophy are better managed together, by musculoskeletal post-critical care rehabilitation and specific physiotherapy programs (17).

Mental health issues are common in patients admitted in ICU for acute respiratory distress syndrome: 40% associated anxiety, 30% experienced depression, 20% had post-traumatic stress disorder (18). Mild cognitive impairment is also very common in the patients with acute respiratory distress syndrome discharged from ICU and may persist up to one year. Specific cognitive assessment at discharge is important, because otherwise a mild cognitive impairment may remain unidentified. Cognitive impairment may impact on professional performance and on societal participation.

For the efficient management of post-intensive care syndrome, a holistic approach is mandatory and should involve a physiotherapist, psychologist and social worker in addition to a cardiologist, pneumologist, and other medical specialists (19).

Nutrition intervention is an essential part of the rehabilitation program for COVID-19 patients, especially if they suffered pulmonary and cardiac distress or in critically ill patients, considering the weight loss, sarcopenia and frailty associated with these conditions. Individually tailored nutrition support is necessary (20). Despite significant muscle loss, an important percentage of post-COVID-19 patients are overweight or obese, indicating sarcopenic obesity, a category with the potential for misidentification of malnutrition.

CONCLUSIONS

Post-COVID-19 rehabilitation represents an important intervention for patients with persistent symptoms and complications after the SARS-CoV-2 infection, especially in those with post-intensive care syndrome. Beyond respiratory and cardiovascular components, post-COVID-19 rehabilitation should be a multidisciplinary patient-centered intervention. Aerobic exercise represents one of the core components of cardiopulmonary rehabilitation, increasing demand upon the cardiopulmonary system and resulting in significant benefits on general fitness and on a wide range of post-COVID-19 problems, such as fatigue, lack of performance in professional and recreational physical activities and

emotional disturbance.

In the context of the paucity of evidence-based guidelines on post-COVID-19 rehabilitation, further clinical research regarding long-term complications of COVID-19 is needed.

NEWS

PREGNANCY-ASSOCIATED PLASMA PROTEIN-A - A LINK IN BREAST CANCER PROGRESSION

Pregnancy associated plasma protein A (PAPP-A) is a zinc-containing metalloproteinase produced by the syncytiotrophoblast whose concentrations increase rapidly in early pregnancy with a doubling time of 3 days before slowing to a more gradual increase until term. PAPP-A regulates the concentration of free IGF-II by cleaving insulin-like growth factor binding proteins (IGFBP), predominantly IGFBP-4. PAPP-A circulates as a large heterotetrametric composed of two subunits of PAPP-A and two subunits of pro-major basic binding protein, which is produced by the cytotrophoblast cell layer of the placenta. PAPP-A measurements are performed exclusively as part of first trimester screening. Although PAPP-A is present in men and nonpregnant women, concentrations are typically < 1 mIU/L, this protein is highly expressed in pregnancy-associated breast cancer tissues. A recent study showed that PAPP-A was upregulated in pregnancy associated breast cancer tissues and breast cancer cells. Overexpression of PAPPA promoted cell proliferation, motility, invasion, and epithelial-mesenchymal transition. Also, the study shows that the PAPP-A is an oncogenic protein highly expressed in PABC tissues and promotes breast cancer progression. The levels of PAPPA in mARN were significantly higher in pregnancy-associated breast cancer (PABC) tissues than in normal breast tissues (n = 30). The protein level of PAPPA was detected by western blot in breast cancer cell lines (T47D, MCF-7, BT549, MDA-MB-231, and MDA-MB-468) and in normal breast epithelial cell MCF-10A. These overexpression's promoted proliferation, migration and invasion of breast cancer cells. Finding a way to suppress the action of this protein may serve as a novel therapeutic target for breast cancer (Zhang J, Zhang Y, Li L, Nian Y, Chen Y, Shen R, Ma X. Pregnancy-associated plasma protein-A (PAPPA) promotes breast cancer progression. *Bioengineered* 2022; 13(1): 291-307. doi: 10.1080/21655979.2021.2000724).

CHALLENGES OF THE DENTAL MEDICAL PRACTICE DURING COVID-19 PANDEMIC AND POST-PANDEMIC PERIOD

The COVID-19 pandemic represented a change of paradigm for dental health care providers as this category of professionals faced unexpected and unforeseen challenges regarding moral decision-making (1).

The first challenge was the interruption of the ongoing dental treatments; dental professionals were limited to telephone consultations, and antibiotic prescriptions sent by e-mail or *WhatsApp*, and ensured only major dental emergencies (uncontrolled bleeding; diffuse soft-tissue bacterial infections with intra-oral or extra-oral swelling or trauma involving facial bones that potentially compromises the patient's airway) and dental urgencies (swelling of gum, cheek or face which; acute oral pain; mouth ulcers prolonged for more than two weeks; bleeding that lasts more than 20 minutes to a patient with recent tooth extraction; fractured tooth which is causing pain and damage to cheek or tongue; traumatized tooth; bleeding due to facial trauma). These measures were requested by higher risk of COVID-19 infection within dental professionals due to face-to-face contact, and the presence of COVID-19 in aerosols (liquid and solid particles suspended in air) and splatter (mixture of air, water, solid substances) frequently formed during routine dental procedures when high-speed instruments are used (2-3). As 91.7% of subjects with COVID-19 have virus in saliva samples (4), dental procedures with high volume of aerosols make ineffective the standard protective measures for patients in the incubation period, unaware of their infection status, or those who conceal their infection (5). Regardless of the degree of community spread, dentists must screen all people who enter the dental setting for symptoms of COVID-19. Dental treatment had to be provided after considering both the risk of delaying dental health care and the risk for dentists of healthcare-associated disease transmission (6). Conservative treatments were the most affected dental procedures during COVID-19 pandemic, followed by periodontal diseases treatment, where almost half of the planned treatments could not be performed (7). The patients between 35 and 74 years were the most affected by the absence of dental caries treatment, endodontic therapy, and periodontal diseases treatments (7). Blockage of routine dental activity has been associated with increased vulnerability of patients to other conditions (caused by increased consumption of antibiotics), as well as the occurrence of functional, biological, or aesthetic complications caused by delayed dental procedures, prosthetic treatments, orthodontic treatment sessions (7). Poor oral health can accelerate the development of other systemic conditions as follows: cardiovascular system pathology, neurodegenerative diseases, diabetes, low birth weight, osteoporosis, and kidney disease (8).

The second challenge was related to the transition to the alert state. Clinicians have adopted a series of measures recommended

by the Romanian College of Dentists, measures aimed at preventing and limiting the spread of COVID-19, as well as protecting members of the professional body; these measures were inspired by similar measures adopted by professional dental associations in the USA, Canada, France (9, 10, 11). The implementation of these measures required the reorganization of the circuits and work protocols in the dental offices that generated the increase in expenses by the additional purchase of protection and disinfection materials (for example, surgical ultraviolet lamps and High Efficiency Particulate Arrestance Filters). In addition, there was a decrease in the number of patients treated per day due to the increase in time required for the preparation of the office and medical staff but also the postponement of elderly patients with associated general pathology. To restrain and mitigate the COVID-19 infection. It was proposed the introduction in dental public and private clinics of screening tools, either rapid molecular testing or saliva point-of-care technology, which should be effective in identifying and isolating the potential contacts and carriers (12).

The new economic conditions have contributed to the reduction of patients' addressability to complex oral rehabilitation treatments. At the same time, the higher percent of population with untreated needs and lower income has increased the burden on public health systems and, at the same time, has reduced the revenues of private dental practices.

In this context, the projects regarding the oral health status of the population in the post-pandemic period must address factors such as socio-economic status, social environment, cultural norms, and the health insurance system. In this post-pandemic period, we must consider the recommendations of World Health Organization for the integration of the oral health into general health promotion strategies and the assessment of the oral health needs through socio-dental approaches, as well as the promotion of oral health within disadvantaged population groups (13).

Complex oral rehabilitation remains, in the post-pandemic period, an area of interest for patients who request the complete restoration of the functions of the stomatognathic system. In this context, it is requested an interdisciplinary management of edentulous patients through the collaboration of specialists in the fields of periodontology, implantology, prosthetics, oral surgery, and orthodontics.

Clinicians are currently focusing on factors that influence the success rate of classical and implant-prosthetic prosthetic treatments: biomaterials, design and surface bioactivity of dental implants, biomechanical factors, quality and volume of bone tissue, surgical technique. Decisions regarding the selection of techniques and materials used in prosthetic and implant therapy imply uncertainties regarding the prognosis of therapy, in relation to the experience and preferences of the practitioner, the preferences and values of patients, and the costs involved (14).

The long-term success of the mucosal support reconstruction techniques is highly related to the individualized analysis of the specific systemic, loco-regional, local parameters and the focus on therapeutic algorithms adapted to each individual case.

Modern imaging techniques used for the diagnostic and assessment of muco-osseous support allows the understanding of the predictive factors and the adoption of adequate informed decisions regarding the implant-prosthetic therapeutic solutions (15).

The development of individualized protocols and algorithms for alveolar reconstruction techniques and addition materials, in relation to the particularities and complexity of clinical cases, is a necessity in the therapeutic management of patients with severe alveolar resorption.

The effectiveness of the oral complex rehabilitation procedures can be significantly increased by the introduction of the digital workflow, from the treatment planning and designing, from implant surgery procedures to the fabrication of individualized prostheses produced by computer-aided design/computer aided manufacturing (CAD/ CAM) technologies (16). Implant-prosthetic therapy assisted by digital systems favors the use of early loading (post-implant 3-6 months) or immediate loading (post-implant first 48 hours) protocols that reduce the number of sessions, reduce the post-operative healing time, and increase patient post-operatively comfort (17). The digital tools and technologies also give a strong boost to various minimal invasive surgical techniques used in the implant stage.

Despite these advantages, before COVID-19 pandemics the current use of the digital technology was still lacking in the clinical dental practice, situation that was linked to the slow adoption of digital technology (18).

COVID-19 pandemic period imposed a larger adoption of the digital devices and technologies. We can predict further enrolling of the dental practitioners in digital courses aiming to gain in-depth knowledge of digital applications and expert systems that optimize diagnosis and treatment plan, as well as support clinical decisions based on causal and probabilistic reasoning in theoretical decision-making schemes.

The widespread use of dental technology in the pandemic period provides patients with the opportunity to fulfill the esthetic demands, to preview the future prosthetic solutions and, by the use of the minimally invasive surgical procedures, to shorten the time required from diagnostic to final implant-supported prosthetic restoration for uninterrupted social and professional life of the edentulous patients.

COVID-19 pandemic period was followed by clinical, economic, legal and social consequences with future impacts on dental practice (19). In this context, professional scientific associations, government authorities, public and private dental care services must design new rules and policies for similar long-term pandemic periods.

PULMONARY REHABILITATION BETWEENA PAST IN SHADOWS AND A BRIGHT FUTURE

BRIEF HISTORY OF PULMONARY REHABILITATION

During the last century numerous data and innovative ideas regarding pulmonary rehabilitation (PR) have accumulated worldwide, coupled with the development of an arsenal of new techniques for investigating and evaluating the respiratory function. It is an important advance in modern medicine and a concern for an expanding pathology. In parallel with humanity's efforts to modernize, aiming for a high degree of civilization, the pathology is also growing. With the industrialization and urbanization of lifestyle, the human body, and especially the respiratory system, is subject to risk factors that are ever growing in harm.

The roots of the PR treatment have their origins in distant history. In the writings of the ancient peoples (Assyrians, Egyptians, Jews, Greeks and Romans) there is evidence of the use of natural physical agents for therapeutic purposes such as air, water, heat and light.

Laennec first described the concept of PR in 1821 and Charles L. Denison, a former patient with pulmonary tuberculosis, was one of the pioneers of respiratory physiotherapy. In 1880, Dr. Denison recommended breathing exercises for the rehabilitation of patients with tuberculosis in his work "Mountain Resorts with Therapeutic Effects" and in 1985 he also published an article titled "Exercises for the Lungs with Disabilities".

In 1942, the National Rehabilitation Association (NRA), the oldest professional member organization in the United States, defined rehabilitation as a restoration of the individual in terms of the medical, mental, emotional, social, and vocational potential of which the patient is capable of. PR is extremely effective for lung diseases and the basic prototype it was founded upon was the patient with chronic obstructive pulmonary disease (COPD).

In 1981, the American Thoracic Society officially supported the PR of COPD patients. In 1984, after extensive study, Dr. John Hodgkin published the paper "Pulmonary Rehabilitation - Guidelines for Success" which included the official definition of PR and the structure of practical PR programs. With the publication of these papers, the interest and involvement of physicians and medical associations has grown, and their contribution has been observed to this day: "American Association for Respiratory Care", "American Association for Pulmonary and Cardiovascular Rehabilitation", "American Thoracic Society (ATS)", "European Respiratory Society (ERS)".

The concept of rehabilitation also entered Romania in 1969, when the statistics of the Ministry of Health estimated that 3% of the active workforce had lost their work capacity and recovery and thus reintegration measures were required. In the 1970s, the managements of the County Sanitary Directorates from Iasi and Cluj offered to

the Ministry of Health a solution to the problem by setting up rehabilitation hospitals in these two university centers that would fully meet the health requirements of modern medicine. By Decree 296 of 1973, the Ministry of Health approved the construction of rehabilitation hospitals in the municipalities of Iasi and Cluj.

In 1974, at the fifth session of the Romanian Academy of Medical Sciences, the first guidelines for PR were drawn, and in recent years we are witnessing an explosion of PR services and various techniques and devices used in the rehabilitation of lung patients. These respiratory therapies complement the pharmacological treatment and represent the cornerstone of the management of these patients.

The year 2006 was a significant year in the history of pulmonary rehabilitation due to internationally publishing the *Joint Declaration on PR by ATS / ERS* while in Romania the *Working Group on Respiratory Rehabilitation of the Romanian Pneumology Society* was created at the proposal of the undersigned, and with the support of the Romanian Pneumology Society Board, as a representative of the Rehabilitation Clinical Hospital and the "Grigore T. Popa" University of Medicine and Pharmacy from Iasi. Research in this field is in full swing worldwide and in our country (1).

PULMONARY REHABILITATION-OBJECTIVES, EVALUATION

PR treatment occupies a central place in patients with chronic lung disease, being recognized by all specialists in the field. The current definition of PR, according to the *Official Report of the American Thoracic Society Workshop* published in May 2021, is based on definitions previously developed, on scientific evidence, by PR specialists, which were published in 1974 and updated in 2006, 2007, 2013 and 2015, respectively. According to this report, "pulmonary rehabilitation is a comprehensive intervention based on an announced patient assessment, followed by patient-friendly therapies, which includes, but is not limited to, training, medical education and behavior change designed to improve the physical and psychological condition of people with chronic respiratory disease and to promote the long-term adherence to health-enhancing behaviors" (2).

Pulmonary rehabilitation is an *extremely effective treatment for people with chronic lung disease*, including post-COVID-19 respiratory sequelae, which is still underused worldwide. The conditions that can benefit from pulmonary rehabilitation are:

a) *lung diseases with obstructive ventilatory dysfunction*: COPD, asthma, bronchiectasis, cystic fibrosis, bronchiolitis obliterans;

b) *lung diseases with restrictive ventilatory dysfunction*: interstitial lung diseases (pulmonary fibrosis, occupational or environmental lung diseases, sarcoidosis, scleroderma, lymphangiomyomatosis, post-COVID-19), thoracic wall deformities (kyphoscoliosis, spondylitis ankylosis) restrictive ventilatory dysfunction;

c) *other pathological conditions*: lung cancer, pre / post lung transplant conditions, pre / post thoracic and abdominal surgical conditions with ventilatory dysfunction, pre / post LVRS (Lung Volume Reduction Surgery) conditions, ventilator dependence, pediatric patients with respiratory diseases, respiratory diseases related to obesity, autoimmune diseases with pulmonary involvement, pulmonary hypertension (3, 4, 5).

Initial assessment of patients for inclusion in the PR program involves: detailed history and a correct clinical examination, assessment of contraindications for the rehabilitation program, assessment of smoking status, assessment of nutritional status, measurement of peripheral muscle strength, assessment of dyspnea and fatigue, performance evaluation of daily activities, quality of life assessment, medical education assessment, respiratory function assessment, exercise capacity assessment, electrocardiogram, echocardiogram, chest imaging assessment, additional needs assessment ± other investigations depending on the patient's comorbidities.

Comprehensive and thorough patient assessment is essential for personalizing the PR program and for effectively addressing the objectives of individual PR programs tailored to the patient's needs. In recent years, new models of PR programs have emerged, which aim to improve patient access, tailored to their needs, including telerehabilitation and low-cost models useful for PR at home. Quality assurance processes for PR programs are important to ensure that any PR service delivers optimal outcomes for patients and health services. The success of these PR models is assessed by the achievement of the essential components of the PR programs and the expected results of the patient, including improved exercise capacity, reduced symptoms, especially dyspnea, fatigue, cough, sputum, chest pain, anxiety and depression, reduced hospital admissions and improved health-related quality of life (6, 7, 8).

PULMONARY REHABILITATION AND LONG-COVID SYNDROME

The onset of SARS-CoV-2 coronavirus in December 2019 in Wuhan, China, and its rapid spread to over 216 countries has had a profound impact on humanity, leading to an unprecedented global crisis, both economically, socially and medically while also representing the biggest challenge we faced after the Second World War.

Experience, as well as studies conducted during this pandemic, have shown us that although COVID-19 is primarily a respiratory disease, the virus can affect other organs and systems of the body, which are manifested by characteristic symptoms. This is mainly due to the ubiquitous distribution of the SARS-CoV-2 virus receptor, a virus that causes systemic disease, with possible involvement of the heart, liver, pancreas and kidneys, causing changes in circulating lymphocytes and the immune system.

The impact of the severity of acute respiratory syndrome-coronavirus-2 may persist in some cases months after the initial illness, requiring individualized assessment and long-term follow-up for early detection of lung sequelae and correction of imbalances.

Long-COVID syndrome is defined as the syndrome that marks what is known so far: the persistence of COVID-19 disease symptoms 6 to 12 months after the acute phase, which are not explained by any other alternative diagnosis. It is characterized by the existence of a symptomatic corollary such as: fatigue, dyspnea, chest pain, cough, anosmia, dysgeusia, migraines, joint and muscle pain, cognitive dysfunction, etc., which proves that there are multiple organs involved (lung, cardiovascular, skin, neuropsychic, etc.), of which the lung suffers in two important areas, pulmonary fibrosis with or without traction bronchiectasis, pulmonary nodules and pleurisy, being the head of the poster,

followed in the second time by lung infections.

There are frequent cases that pass the acute period and are transferred from *COVID-19* to *non-COVID-19* services, due to the persistence of these accusations or their aggravation, the dyspnea being severe, with immobilization in bed and oxygen requirement between 10-15 L/min or non-invasive ventilation. It is true that in terms of symptoms, after post-COVID-19 recovery, 87.4% of patients have at least one persistent symptom, only 12% are asymptomatic after 2 months and in 51% of patients the quality of life is affected. These expressions are only the tip of an iceberg that can take a turn of gravity at any time (9).

In a clinical approach to post-COVID-19 status, a key concept is highlighted, namely the universal issue of rehabilitating post-SARS-CoV-2 sequelae, which is a complex concept that is not limited to the Real Time Test-The Polymerase Chain Reaction (RT-PCR) negative or the presence of anti-SARS-CoV-2 antibodies. *The same approach points out that there are still many unknowns related to COVID-19 disease, especially in the post-acute phase, in terms of the persistence of symptoms and the severity of long-term respiratory sequelae, as well as other complications (neurocognitive, cardiac, renal, etc.)* (10).

To develop a rehabilitation program for post-COVID-19 patients, the PR team has a well-recognized and widely accepted option: *reproducing the PR algorithm for patients with chronic pulmonary disease (COPD).* However, these patients need precise triage and a set of basic fundamental assessments to provide special rehabilitation programs (in-hospital, outpatient, tele-coaching, telerehabilitation, home rehabilitation), because the trajectories of phenotypes are very different and are not always related to hospitalization in the intensive care unit.

The benefits of PR programs for various chronic lung diseases have been demonstrated in numerous studies over time, and increased findings are currently being made on the favorable short- and long-term effects of including post-COVID-19 patients in these programs, *highlighting the crucial role of rehabilitation specialists* (11).

Long-term follow-up is a new challenge and is strongly recommended in these patients to detect time-consuming lung sequelae and appropriate management for their dysfunction. *Monitoring of post-COVID-19 patients* in specialist outpatient clinics and/or hospitals allows early assessment of symptoms (fatigue, dyspnea, cough, chest pain, depression and anxiety, etc.), of physical performance and lung function, which allows the application of the PR program, as well as the organization and tracking of this complex treatment. Early complex and comprehensive PR intervention in these patients certainly demonstrated a significant reduction in symptoms at 1, 3, 6 and 12 months, respectively, after the acute episode and an increase in physical and cognitive performance, and overall quality of life (12, 13).

PULMONARY TELEREABILITATION

The last two years have presented us with a brand-new challenge: *telemedicine*, which is defined by the World Health Organization as "the provision of healthcare services, where distance is a critical factor, by all healthcare professionals, through the use of information technologies and communication, for the exchange of valid in-

formation for the diagnosis, treatment and prevention of diseases and injuries" in which *pulmonary telerehabilitation* (tab. I) occupies an important place (14).

TABLE I.

Pulmonary telerehabilitation: advantages and disadvantages (15, 16)

Advantages	Disadvantages
• The patient is in a family environment; • Allows the patient to be autonomous, confident; • The rehabilitation process is facilitated, and a real acceleration can be observed; • Telemedicine / telerehabilitation removes geographical and distance barriers; • Everything can take place on secure medical communication platforms, where data confidentiality is strictly maintained; • Reduce healthcare costs; • Saving the time needed to travel home; • Wider access to the PR program; • The PR program can be monitored;	• Patients need to know technology; • Requires internet connection; • Inability to perform the PR program without the presence of a qualified and trained medical staff for what it means to assist in pulmonary rehabilitation; • There is currently no legal framework in Romania to regulate the activity of telemedicine; • Lack of transparency regarding data security; • Lack of information and trust regarding specific eHealth solutions among patients, citizens and healthcare professionals.

Telerehabilitation at home is a useful option for patients who are in the period after an acute illness and cannot be taken over by the rehabilitation centers but need to start the rehabilitation program as soon as possible. Although pulmonary rehabilitation is a well-established therapeutic method, with proven benefits, 8-40% of patients referred for hospital PR programs do not adhere to them, while 10-30% of those who start the program do not complete it.

Telerehabilitation is a therapeutic tool that can be used successfully in patients with chronic respiratory diseases. Studies comparing telerehabilitation with standard rehabilitation have shown favorable results in increasing exercise capacity and reducing symptoms, as well as improving the quality of life of patients with chronic lung disease (17).

Telemedicine has proved its worth in the midst of the pandemic, when health and distance rules made it inaccessible for patients to participate in rehabilitation programs, including patients with SARS-CoV-2 infection, both in the acute phase and the post-COVID-19 state, manifested predominantly by respiratory symptoms during rest and exertion, for which PR is required. In this context, telerehabilitation has been an extremely important aid. It has been used successfully in Wuhan hospitals, where patients with COVID-19, isolated in wards, have been given, through a telephone application, models of aerobic exercise, resistance training with elastic bands, and exercises for training the respiratory muscles, in the form of videos or written recommendations. The exercises were also recorded, the application having a symptom monitoring system, which was transmitted from patients to doctors.

In a multicenter study conducted in Australia, which assessed the access of patients with chronic respiratory diseases to technology, out of 254 participants, 92% had access to at least one electronic device,

70% a tablet or a computer and 85% a mobile phone; 60% of patients were willing to access telerehabilitation (18).

Technologies used to perform pulmonary telerehabilitation include home video conferencing, the use of smartphones, tablets, web platforms and pedometers connected to the internet, virtual reality and augmented reality. Progress in telemedicine focuses on augmented reality, which is based on the concept of real-time, barrier-free interaction. Augmented reality differs from virtual reality by creating a real-time physical environment using four computer-generated sensory inputs (sound, video, graphics, or GPS data), while virtual reality detaches contact from reality. *The future of medicine is geared towards augmented reality, although there is currently very little evidence of its use in rehabilitation* (19, 20).

The use of technology provides patients with chronic respiratory diseases with extensive access to pulmonary rehabilitation. The technological devices are multiple and can be used singularly or combined and are in a permanent development.

CONCLUSIONS

The history of pulmonary rehabilitation is interesting. What appeared to be a field or an uncertainty with obscure benefits, it is now supported by evidence classified by experts to be of the highest standard. There is also hoped that the upcoming years will provide even newer and more exciting ways for a wider and more important role of PR in a futuristic version of the field.

Specific assessment of each patient to achieve adequate results, long-term effects and maintaining the benefits of PR in the individual patient, the most appropriate access of PR to the early onset of disability, overcoming potential barriers, raising awareness of this science to people/patients and to professionals, the incorporation of new technologies and the principles of e-health are all real frontiers to be explored in order to improve PR.

This is an interesting and opportune time for pulmonary rehabilitation, which can bring new opportunities and allow the exploration of new areas in search of improvement. Overall, the future of pulmonary rehabilitation will include more patient options and greater program customization, while comprehensive patient assessment should continue to be a benchmark for all programs and models.

EDITORIAL

TYPE 2 DIABETES MELLITUS: ANOTHER ONGOING SILENT PANDEMIC

Type 2 Diabetes Mellitus (T2DM) is a chronic metabolic disorder, with an increasing prevalence in the past two decades being associated with impaired insulin secretion, resistance to peripheral actions of insulin, or both which cause persistent hyperglycemia (1). In patients with T2DM, persistent hyperglycemia can damage different organ systems in combination with other metabolic abnormalities, which can result in life-threatening and disabling health complications. The most common of these complications are microvascular (retinopathy, nephropathy, and neuropathy) and macrovascular ones, which increase cardiovascular disease risk by two to four times (2). According to the World Health Organization (WHO), approximately 422 million adults between the ages of 20 to 79 years had T2DM in 2022 affecting 6% of the global population (3). In Romania, the prevalence rates are similar, approximately 5% of the population had this metabolic disorder. Moreover, 7 out of 10 patients with T2DM in our country, had been diagnosed with long-term complications of diabetes (e.g., peripheral arterial disease, chronic kidney disease, retinopathy or blindness) (4).

Obesity, metabolic syndrome (MetS), and non-alcoholic fatty liver disease have all become more common in recent years, along with T2DM prevalence. Type 2 diabetes (T2DM) and non-alcoholic fatty liver disease (NAFLD) are linked in both directions; NAFLD causes insulin resistance (IR) and T2DM through several pathways, but T2DM also promotes liver disease as a separate risk factor (5). Although NAFLD was first considered to be the hepatic manifestation of MetS, there is now convincing evidence that NAFLD is a major contributor to MetS, and that hepatic involvement is one of the components of multisystemic organ involvement (6). NAFLD is now considered a global epidemic that affects 1 in 4 persons worldwide, with a prevalence estimated to range between 25% and 30%. The fact that the prevalence of NASH is rising along with the rates of MetS and its components is even more concerning with the main risk factors for NASH being obesity, T2DM, and MetS (7). Moreover, NAFLD is more common in people with T2DM-roughly 75% more common than it is in people without diabetes. Patients with severe steatosis had a higher chance of acquiring T2DM, and those with NAFLD had a risk of developing it that was at least twice as high as that of subjects without NAFLD. Also, patients with NAFLD with T2DM had a 2.2-fold greater risk of all-cause mortality (8).

The guidelines recommendations are in conflict when it comes to screen T2DM patients for liver steatosis and fibrosis. Therefore, according to European Guidelines, patients with NAFLD can be screened for T2DM by measuring their fasting blood sugar or hemoglobin A1C (9). In addition, diabetic patients with increased ALT or hepatic steatosis should be screened for NAFLD, according to the American Diabetes Association (10). In-

stead, the American Association Society of Liver Disease disagrees with the routine screening of T2DM patients (11). Due to its simplicity and low cost, abdominal ultrasonography (US) is one of the screening methods that is most frequently used. According to a meta-analysis, this approach had a specificity around 80% compared with liver biopsy for detecting mild and severe steatosis. The US has the drawback of relying on the operator to determine the degree of steatosis in obese individuals or those with moderate steatosis (12). On the other hand, vibration-controlled transient elastography (VCTE) with controlled attenuation parameter (CAP) is a quantitative method that has a higher sensitivity and specificity for assessing hepatic steatosis. Additionally, assessments of the CAP numerical values correlate with the histological degree of steatosis (13).

Weight gain and obesity are the most important predictors factors for developing T2DM. These relationships most likely originate from inflammatory stimulation of adipose tissue, which causes insulin resistance (14). Recently, WHO estimated that 650 million people globally are ob ese and 2 billion adults worldwide are overweight (15). By 2025, it is anticipated that 2.7 billion adults would be overweight, nearly 1 billion individuals will be obese, and 177 million persons will be extremely obese if current trends continue. According to predictions, 1 in 5 women and 1 in 7 men would have obesity by the year 2030 (16). Obesity is defined by the WHO as an excessive buildup of body fat that is clearly related with health concerns; because of its ease of use, the body mass index (BMI) is most frequently used to measure obesity. By dividing the body weight in kilograms by the square of the height in meters, the BMI is determined. Grade 1 obesity is defined as having a BMI $\geq$ 30 kg/m^2, grade 2 obesity as having a BMI $\geq$ 35 to 40 kg/m^2, and grade 3 obesity as having a BMI $\geq$ 40 kg/m^2 (17). There is a widespread understanding that obesity, whether it be a condition that predisposes to disease or a disease in and of itself, needs to be treated and, more importantly, prevented (particularly in children), given its serious comorbidities, mortality, and financial implications (18). The prevalence of NAFLD and T2DM, two chronic disorders linked to obesity, has increased as this silent pandemic has spread around the world. NAFLD is the obesity-related noncommunicable illness with the greatest rate of growth, and it is a reliable indicator of liver and cardiovascular mortality (19). The global food system has seen significant changes over the last few decades, and billions of people are now daily exposed to processed foods and beverages high in energy that multinational firms have increasingly sophisticatedly marketed (20). As a result, it is challenging to imagine how individual-focused initiatives, like weight-loss programs or healthy eating campaigns, can be successful without laws that change the underlying environmental factors (19).

Several studies that were recently published found that Romanian patients with T2DM, had a prevalence in NAFLD of approximately 73%, and the main prognostic factor of steatosis was the severity of liver fibrosis (21, 22). Using VCTE, Trifan *et al*. found that the prevalence of advanced fibrosis was 11.7%, and the prevalence of cirrhosis was 13.6%. Moreover, 40.8% of the subjects included in the study had a BMI$\geq$ 30 kg/m^2 and was associated with severe steatosis and fibrosis (advanced

fibrosis and cirrhosis) (21). In another study, which included medical students by Nastasa *et al*. found that half of the obese subjects had NAFLD (23).

T2DM, obesity and NAFLD are regarded as risk factors for each other. This causes us to be cautious about the potential effects of early detection of one disease in the presence of another. Additionally, the progression and consequences of each disease are influenced by the presence of NAFLD, T2DM and obesity (24). The same lifestyle adjustments, oral hypoglycemiant drugs, and bariatric surgery as a last-resort therapy option are the key components of their prevention and management plans, which have been found to have an impact on the management of NAFLD, T2DM and obesity.

EDITORIAL

OBESITY: THE COVERED RISK OF CANCER

Almost all developed and developing nations now experience a sharp increase in the incidence of overweight and obesity, which affects 60-70% of the adult population in industrialized nations and is more common in females and metropolitan regions (1). Overweight and obesity are now more common over the world than ever before-in adults, by 27%, and in children, by 47% (2). When a person's caloric intake exceeds their metabolic and physical activity-related energy expenditure, obesity results. Fat is deposited and accumulates as ectopic fat tissue, increasing the risk for several disease entities as a result of excessive or aberrant fat tissue formation that surpasses genetically and epigenetically established adipose tissue stores (3). The World Health Organization defines obesity as having a body mass index (BMI) ≥30 kg/m^2 (≥30 kg/m^2 as grade 1, ≥35 kg/m^2 as grade 2, and ≥40 kg/m^2 as grade 3), with normal values being between 18.5 to 24.9 kg/m^2 and overweight being intermediate values of 25 to 29.9 kg/m^2 respectively (4). According to these criteria, roughly 35% of adults in the USA over the age of 20 are already overweight, and the prevalence of obesity is expected to rise to 42% in persons over the age of 18 by 2030 (5).

With an estimated 14.1 million incident cases and 8.2 million fatalities per year, cancer ranks as the second largest cause of death globally (6). Obesity is a recognized risk factor for a number of cancers, in addition to the well-established cancer risks factors such as genetic predisposition, ionizing radiation, nicotine use, infections, unhealthy diet, alcohol intake, sedentary lifestyle, and other environmental exposures (7). Due to the rising prevalence of risk factors, particularly obesity and metabolic syndrome, cancer incidence will continue to rise (8).

According to global estimates, obesity and overweight were linked to 5.5% of cancer cases in the UK, while others asserted that the relative risk of cancer death linked to obesity was roughly 14.2% in men and 19.8% in women (9). The link between obesity and cancer is fairly strong, particularly when it comes to gastrointestinal (GI) tract tumors, where being overweight increases the risk of cancer by 1.5-2.4-fold. The types of cancer that are most strongly linked to obesity have been defined by several studies to include breast cancer in postmenopausal women, colorectal cancer (particularly in men), hepatocellular carcinoma, endometrial cancer, ovarian cancer, esophageal adenocarcinoma, gastric cancer, pancreatic cancer, gall bladder cancer, thyroid, kidney cancer, multiple myeloma and meningioma (10).

Numerous theories have been put out to explain how obesity may raise the risk of some malignancies. As a result of the release of mitogenic signals, the local microenvironment that supports tumor growth also drives cell survival mechanisms and the development of tolerance in cytotoxic host T cells (11). The overproduction of estrogen by fat tissue, also known as adipose tissue, has been linked to an increased

risk of developing breast, endometrial, ovarian, and other cancers. Increased blood levels of insulin and insulin-like growth factor-1 are common in obese people (IGF-1). Insulin resistance causes high insulin levels, or hyperinsulinemia, which precedes the onset of type 2 diabetes, another proven cancer risk factor. Increased insulin and IGF-1 levels have been linked to an increased risk of endometrial, renal, prostate, and colon cancers (12, 13).

Chronic inflammatory diseases like gallstones or non-alcoholic fatty liver disease are frequently seen in obese people. These circumstances can result in oxidative stress, which damages DNA and raises the risk of developing biliary tract and other malignancies (14). Adipokines, which are produced by fat cells, are hormones that can either promote or inhibit cell growth. For instance, as body fat accumulates, the blood level of an adipokine called leptin rises as well. Leptin levels above a certain point can encourage the development of abnormal cells. Adiponectin, another adipokine, may have antiproliferative properties that inhibit the development of tumors but is less prevalent in obese individuals than in individuals with a healthy weight. Mammalian targets of rapamycin (mTOR) and AMP-activated protein kinase are two more cell growth and metabolic regulators that fat cells may directly and indirectly affect. Obesity may also increase the risk of cancer by reducing tumor immunity and altering the mechanical characteristics of the tissue that surrounds growing tumors (13). Obesity can complicate screening and management in addition to having biological implications. Thus, women who are overweight or obese are more likely to get cervical cancer than women who are of a healthy weight, most likely as a result of less efficient cervical cancer screening in these people (15).

According to a nationwide cross-sectional study using BMI and cancer incidence data from the US Cancer Statistics database, from 2011 to 2015, about 74,690 new cases of cancer in women and 37,670 new cases of cancer in men aged 30 and older, respectively, were attributable to excess body weight (overweight, obesity, or severe obesity). As high as 51% for liver or gallbladder cancer and 49.2% for endometrial cancer in women and 48.8% for liver or gallbladder cancer and 30.6% for esophageal adenocarcinoma in males were among the percentages of cases where increased body weight was blamed (16). According to a recent study by Sung *et al.*, increased body weight contributed to almost 3.9% of all cancer cases globally in 2012 (544,300 cases), with women bearing a greater share of the burden (368,500 cases) than males (175,800 cases). Less than 1% of malignancies related to excess body weight occurred in low-income nations, while 7% to 8% occurred in several high-income Western nations as well as Middle Eastern and Northern African nations (17).

In several studies, it was discovered that obese individuals who reduced weight had lower rates of breast, endometrial, colon, and prostate cancers. For instance, a major prospective study of postmenopausal women found that an intentional weight loss of more than 5% was linked to a decreased risk of malignancies linked to obesity, including endometrial cancer. Unintentional weight reduction, however, was not linked in this study to a higher risk of cancer (18). Teras *et al.*, found that sustained weight loss was linked to a decreased risk of breast cancer among women more than 50 years old (19). Other scientific research has shown that bariatric surgery reduces

the risk of cancer overall, of hormone-related cancers including breast, endometrial, and prostate cancers, and of obesity-related malignancies such as postmenopausal breast cancer, endometrial cancer, and colon cancer in people with obesity, especially in women (20-22).

In conclusion, there is considerable evidence linking cancer, insulin resistance, adipokines, and chronic inflammation brought on by obesity. Determining the ontological function of adipocytokines and their interplay in obesity-related cancer etiology requires additional basic and translational study. It is anticipated that more prospective and long-term research would identify a wide range of obesity-related biomarkers and assess their clinical value in cancer prognosis and monitoring. With regard to public health, lifestyle therapies like weight loss, increased physical activity, dietary changes, and bariatric surgery may be able to reverse the malfunction and inflammation of the adipose tissue that is linked to obesity and may slow the development of cancer.

EDITORIAL

ARTIFICIAL INTELLIGENCE IN CARDIOLOGY

"Artificial Intelligence is the new electricity"
Andrew Ng

Traditional medicine was, and still is, based on history, physical signs, routine tests, imaging and molecular data. In each stage of the process for the final diagnosis and the treatment plan medical thinking is a real help. Medical thinking over time has evolved in parallel with the evolution of medical science.

Training for effective medical thinking need years of study, and the elaboration of the diagnosis also consumes time, and in some fields, we need experts (other preparation time, another time to elaborate the diagnosis). Of course, we have to admit that medical thinking has a subjective side.

The great medical achievements of the 20th century was the following: electrocardiogram-1903-Einthoven; cardiac catheterization -1929/1941 – Forssman / Cournand; echocardiography -1954 - Elder and Hertz; coronary angiography -1958-Sones; invasive cardiology -1978 - Gruentzig. Computed tomography, magnetic resonance imaging, optical coherence tomography can be added...

The 21st century, in the first 2 decades, is dominated by two scientific achievements: genetic and artificial intelligence.

What is artificial intelligence?

There are many definitions, but this one seems to be the clearest: "... computer systems performing the tasks that normally require human intelligence" (1).

The avalanche of data, the "flood of data", which exceeds the power of human imagination, is stored by computers with a capacity that is hard to imagine (every day 2.5 exabytes (2.5×10^{18}bytes) are created and can thus be stored over ½ of all the words ever spoken in the whole world (including telephone conversations) (2) .

This data has been called "**big data**". (fig 1)

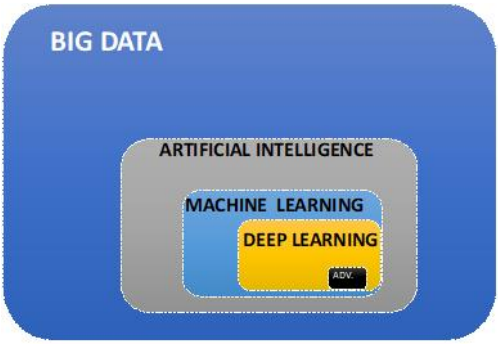

Fig. 1. Components of the artificial intelligence. ADV-advance deep learning

In this „avalanche of data" **Artificial intelligence** (AI), is programmed to imitate human behavior, so AI works with human-made programs and algorithm. Within AI has been developed so called automatic learning, **machine learning**, when computers learn without programs, through examples from the hundreds and thousands of received information (e.g., electrocardiograms, computed tomography or other data).

Here man has only the role of supply of data in the sense that he provides the examples to the system. The human being trains the system, and the system no longer needs programs to function.

Later a complex network of neurons, artificial neurons, was developed, neurons that transmit information from one to another, gathered from the immensity of data, information that they are processed by the artificial neuron network without being understood by human intelligence. This stage is known as **deep learning.**

In deep learning the information collected from different sources enters the system, the information is processed and exchanged with other neurons from many layers and finally conclusions (output) are drawn, and decisions are made (fig. 2).

Conclusions are drawn, quite good, even very good. Nobody knows, nobody understands until today how to get a certain conclusion. For this reason, this part is known as **black box** and creates a big headache for everyone. **As AI becomes more advanced, it is less understood by humans**. Recently a new sub-group called **advanced deep learning** has emerged ! (3).

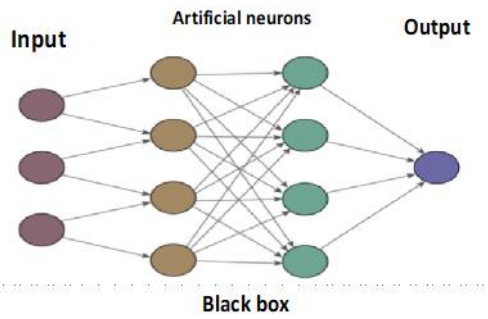

Fig 2. ***Deep learning***. The data entering the system are processed by the neural network and the result is released. It is not known how the result is reached (3)

Although this concept of AI was started in the 1950s by Alan Turing and amplified by Jack Good in the 1970 its development has been done in recent years (because the computers were not up to store and process a big data) with increased velocity (4).

Today AI has 3 major applications in medicine: a) disease prevention and diagnosis; b) faster development of medicines and vaccines (see the anti-COVID-19 vaccine) and c) gene editing.

We will discuss here the relationship between AI and cardiology.

AI has many applications in cardiology in this time and especially in the near future.

Thus, AI can read images or analyses ventricular function, to diagnose valvular heart diseases, arrhythmias, congenital heart diseases reading electrocardiography (fig. 3).

Electrocardiography. Its interpretation can be time-consuming and challenging at times. Automated ECG interpretation is widely used, from many years, with various limitation and over-reading.

Some years ago, in 2002, with my colleague Dr. Ioana Stoian, we have published a book on electrocardiography (5) where one chapter (64 pages), out of the 4 chapters of the book, was dedicated to the electrocardiographic traces read by the computer. We were drawing attention to the erroneous interpretations of computer algorithms and inviting doctors to learn the electrocardiogram well.

Today things are different, apart from the automatic good reading of the electrocardiogram, AI can recognize valvular heart diseases, congenital heart diseases, rhythm disorders, cardiomyopathies and even ventricular function !

Atrial fibrillation is one of the most

common arrhythmias.

Today various mobile devices can be used for detection of atrial fibrillation, these include smartphones, smart bands or smartwatches and earlobe sensors (6).

AI can interpret electrocardiograms during sinus rhythm and was able to find out whether a patient had experienced atrial fibrillation previously and whether it would occur latter (7). This, like other "achievements" of AI, is very curious and still difficult to understand for me.

For many years AI has been a real help in electrophysiology studies.

AI and ECG can recognise left ventricular ejection fraction. Z. Attia *et al.* tested a set of 52.870 patients with ventricular dysfunction (EF <35%), with 12-lead ECG and showed sensitivity 86.3%, specificity 85.7% and accuracy 85.7%. (8).

The ability of the algorithm to read an ECG and see if the FE is low is very important for daily practice, for prevention and for medical research.

Another example: one program was instructed to identify the presence of a low left ventricular ejection fraction from 100,000 ECG (plus other bonus data).

The result was 0.93 (area under the curve), very good! In a recent randomized trial published in Nature Medicine, Yao and colleagues illustrate the power of utilizing AI-enabled ECGs to identify individuals with reduced heart function (9).

Now, using AI-assisted interpretation of ECGs are able to tell us much more. The electrocardiogram with the help of AI can indicate a certain valvular heart disease, for example aortic stenosis (10) mitral stenosis and can evaluate pulmonary hypertension (11, 12) (fig. 3).

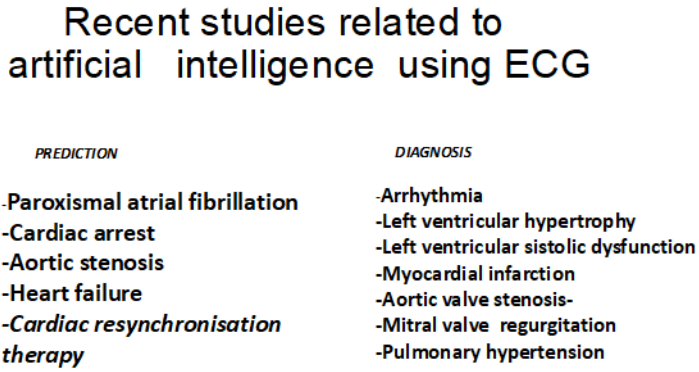

Fig. 3. Recent studies related to artificial intelligence using electrocardiography

Cohen-Shelly *et al.* (10) developed and validated an AI model for detecting aortic stenosis using electrocardiography, they have shown that AI using ECG can identify patients with moderate or severe aortic stenosis and might be able to predict developing aortic stenosis! They have screen ECG and Echo 258,607 patients. In the test group, (102,926 (40%) randomly selected subjects) the AI-ECG patients was positive with the area under the curve of 0.85. The sensitivity, specificity, and accuracy were 78%, 74%, and 74%, respectively (fig. 4).

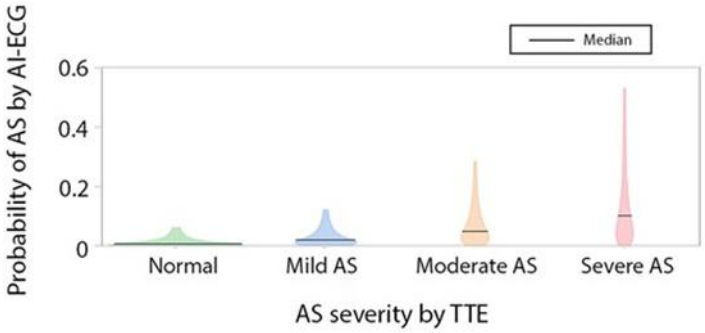

Fig. 4. The probability of aortic stenosis positive labelled by AI-ECG compared with Echo (25) AS-aortic stenosis; TTE- transesophageal echocardiography

Cardiovascular imaging

The first applications of AI in cardiology were possible in digitally acquired images including Echocardiography, Cardiac CT (Computed Tomography) and MRI (Magnetic Resonance Imaging) as well as nuclear imaging (13).

Echocardiography

Echocardiography as a technique has advanced very quickly thanks to computers and advance as an interpretation thanks to artificial intelligence. The results of the echocardiographic examination depend, till now, on the echocardiographer and for this reason this examination has an important subjective part.

Today AI has changed that. Cavity size, wall thickness, ejection fraction and multi-parametric Doppler are automatically calculated and displayed (14).

Now with the aid of AI some diseases are also recognized, such as hypertrophic cardiomyopathy, constrictive pericarditis. Very important for a clinician is the differential diagnosis between constrictive pericarditis and restrictive cardiomyopathy (very difficult diagnosis) and between hypertrophic cardiomyopathy and athletic myocardial hypertrophy.

Cardiac computed tomography (CCT)

CCT is used often for coronary angiography and specially to determine the location and extent of atheromatous plaques in the coronary vasculature as well as for calcium scoring.

Motwani *et al.*, have studied 10,030 patients with suspected coronary artery disease with CT angiography and follow-up the patients during a 5-years. 25 clinical and 44 CT angiography parameters were measured. The AI approach was a significantly better predictor of a 5-year mortality, in comparison to the clinical or CT angiography alone (16).

Recently, in a multicenter study, was developed and validated a deep system for measures of plaque volume and stenosis severity (17). Another research has been used AI for automatic estimation of CT coronary angiography fractional flow reserve (FFR) with good agreement between AI derived values and those which were invasively measured (18).

Cardiac Magnetic Resonance (CMR) is used for the diagnosis of cardiomyopathies, congenital heart disease, valvular heart disease, ischemic heart diseases, pericardial lesions, and cardiac tumors. AI can help to a more efficient scanning and accurate interpretation process: image construction,

image segmentation and image quality control (19).

In a recent trial of 1,348 patients with hypertrophic cardiomyopathy, a new AI driven CMR technology named virtual native enhancement (VNE), was used to generate images identical to the standard Late Gadolinium Enhancement (LGE), without the need of a gadolinium-based contrast agent. VNE resembles conventional LGE but does not require intravenous access or administration of contrast ! (20).

*Cardiac resynchronization therapy (CRT***)**

Conventionally, patients eligible for CRT implantation have greater benefit on reduction of mortality and should have an ECG morphology with Left Bundle Branch Block and QRS duration ≥ 150 ms. Around 30% of patients meeting these criteria and receiving an implant, do not experience clinical benefit from CRT. A model, with the aid of AI, for better discrimination of the risk (mortality) were developed for prediction of evolution post-CRT and with a 2-fold change in survival (21).

Other applications

An algorithm for heart murmur detection was developed: pathologic cases were identified with sensitivity of 93%, specificity of 81%, and accuracy of 88%. AI has a potentially useful screening tool for valvular heart disease in a general population.

A recent interesting example: a group of Chinese scientists developed a convolutional neural network (CNN) which can detect coronary artery stenosis > 50%, (stenosis documented by angiography)), *via* analyzing the patient's facial photo (!) to 5,796 patients with an 85% sensitivity and 54% specificity (higher than the standard prediction scores) (22).

Single-photon emission computed tomography (SPECT) stress testing. AI methodology has been applied in this modality, to improve image acquisition, image reconstruction and automated quantitation (3)

I would like to make a clarification here. I don't want it to be remembered that I have unlimited confidence in AI, that all the data is correct, unchangeable. I am convinced that AI brings support to our activity, to life in general and to medicine in particular, but we must be careful about limits, exaggerations, dysfunctionalities and the impact on people and, in our case, on doctors. AI should act to support and not replace the physician, but as Erick Topol says that "doctors who will use new technologies & AI will replace doctors who will not use it" (23)

Remains to be discussed who is responsible for the AI wrong results.

The application of AI in Cardiology is still in its infancy. It is expected clinical validation, implementation as well as regulation. Food and Drug Administration (FDA) has released a regulatory framework to establish safe and effective AI- based medical devices. (24). The European Union has also proposed a regulatory framework on the use of AI - technology (25).

In the future, AI will have an important role in the prevention of diseases and in the treatment of the diseases as early and efficiently as possible.

Cardiologists should educate themselves in the development of AI and utilize them in their practice.

There are many ongoing studies/trials regarding AI and cardiology in different fields such as: preventive cardiology, cardiovascular imaging, electrocardiography, heart failure, interventional cardiology and we are waiting for the results in the follow-

ing years (26)

The role of doctor in the era of AI

Doctors will have to remain the ones to make the final decision

For patients doctors will provide explanations, humanity, empathy.

The question is whether in the future will be better than today? Possible, if we consider that the medical error is a third cause of death after cardiovascular diseases and cancer (27)

In conclusion, medical thinking still proves its value, and we have an obligation to develop it and induce it to the younger generations.

It is clear that AI exhibits significant potential in the field of cardiology, it can improve diagnostic accuracy and support clinical decisions for many diseases.

Artificial intelligence in the future will be an integral part of medicine.

It is important to prepare the new generation of doctors and the new generation of teachers regarding the concept of AI and the usefulness of this concept.

EDITORIAL

SUDDEN DEATH IN THE CARDIOLOGIST'S VIEW - BETWEEN LITERATURE AND EPIDEMIOLOGY

I have chosen a topic that is most often talked about in whispers. Why ? Because both, whispering and silence hide fear. All of us, we must admit, are afraid of death. Death is a problem for us doctors, only to the extent that we face it most often, being obliged to "ascertain" and "declare" it.

I have been a cardiologist for over 30 years in an emergency hospital where, from the first time witnessing a dying patient, I had the strange feeling that death is lurking around the corner and that, in fact, we are working with it next to us.

The problem of death and its analysis as a phenomenon, concerned both the philosophers of antiquity and those of our days, writers, poets, psychoanalysts. Allow me to revive one of the now famous quotes of Seneca which said that "from the moment we are born, time begins to take back our life". I've lived ever since dominated by the same feeling that sometimes, no matter what we do, what we think, we know how to do, and even if we are doing everything, death comes when it wants. "Nothing is more certain than death, nothing more uncertain than its moment" (said one the most famous Romanian writers - Liviu Rebreanu).

Many centuries later after Seneca, Sigmund Freud, who is considered the founder of psychoanalysis, stated that "The purpose of life is death", a phrase which, beyond the philosophical substrate, in turn caused a wave of confusion. Sometimes we experience the feeling of uselessness in a world where everything seems to be organized by others and we just keep moving forward. Sometimes the disease has its own course that doesn't seem to be influenced by "how well prepared" we are. "I did everything" seems meant to excuse us only in front of our own conscience, in front of those around us, in the eyes of divinity. In fact, no one really knows what "Everything" means and where it stops.

"I think I got deathly ill the day I was born" - the poet Marin Sorescu said very beautifully in his poem entitled "Illness". Comparing his own life with a relentless, incurable disease, the poet does not express his feelings, but suggests them. Moreover, Sorescu's poetry is impregnated not only with symbolic elements, but also with Parnassian elements. Life, death and the state between the two are deeply and precisely sectioned and presented. Borrowing the ideas and concepts of the great philosopher Artur Schopenhauer, from ideas published in "The World as Will and Representation", he does not consider that there is a clear opposition between life and death, but on the contrary - they intertwine: death contaminates life, without necessarily ending it.

From a medical point of view, sudden death is defined as a "natural, cardiac death, characterized by a sudden, rapid and unexpected loss of consciousness, occurring within the first hour after the onset of symptoms of an illness, in persons with known illnesses or unknown". Pre-existing

heart disease may be known but the time and manner of death are unexpected. Controversy exists and remains as to the circumstances in which an unexpected death can be called "sudden" and how the cardiac nature of the cause death can be proven. Sometimes sudden death can be preceded by prodromal phenomena, vaguely defined as malaise, weakness, sometimes palpitations, convulsions but sometimes they are absent, especially in the case of deaths that occur during sleep. Cardiac arrest is not equivalent to death. The latter means brain death or in medical terms - failure of resuscitation, absence of electrical / mechanical activity of the heart and absence of brain activity after cardiorespiratory resuscitation maneuvers (1).

The fundamental concepts on which the definition of sudden death is based are the non-traumatic nature of the event and the fact that the death must be unexpected and instantaneous (quick, max one hour). In a very simple classification for current medical practice, sudden cardiac death can be "coronary" or "non-coronary", starting from the premise that myocardial infarction continues to remain the most common cause of sudden death in adults.

The most important and unequaled cause of death in the adult population in the industrialized world is sudden cardiac death caused by coronary heart disease. In approximately 5-10% of cases, sudden cardiac death (SCD) occurs in the absence of ischemic heart disease or congestive heart failure.

They are excluded from the definition of sudden death - "Instant deaths" that occur quickly and unexpectedly in the evolution of severe diseases in which death is predictable (e.g., neoplasia, cirrhosis) or of states of hemodynamic or biological imbalance, as well as "Violent deaths" by accident or post-traumatic etc.

If we talk about the incidence, according to the statistics in the USA, a number of 300,000 - 350,000 SCDs are estimated annually, and according to the reports of the European Society of Cardiology, sudden cardiac death has an incidence between 0.36 and 1.28 per 1,000 inhabitants, with the mention that only victims examined or resuscitated by emergency medical services were included in these studies and that the data underestimate the true incidence in the general population (1). The incidence is also higher among men aged 60 to 69 with a history of cardiovascular disease, with rates of up to 8 per 1,000 per year reported. In Maastricht, a population-based study that followed all cases of cardiac arrest occurring in victims between 20 and 75 years of age recorded a total annual incidence of SCD of 1 in 1,000 per year. Overall, 21% of all deaths in men were sudden and unexpected compared to 14.5% in women. According to the same statistics, 80% of out-of-hospital cases occurred at home and approximately 15% on the street or in public spaces, and 40% of all cases of SCD occurred without witnesses. The incidence is higher in industrialized countries (which seems logical, especially related to the stress factor associated with an unhealthy lifestyle) and lower in underdeveloped or developing countries (2, 3).

Statistics estimate that 65% of SCD occur outside the hospital, of which 80% occur at home or during transport and 15% - in public places. There is also talk of a circadian mood, SCD being more frequent in the early hours of the morning (6-10 a.m.). The annual incidence in the general population is estimated at 1-2/1,000 people, but it increases 10 times in those with in-

creased cardiovascular risk. The maximum incidence registers 2 peaks: the first between birth and the age of 6 months (sudden infant death syndrome), and then drops steeply, remaining at a low level throughout childhood and adolescence and begins to increase in young adults, reaching a second peak between 45 and 75 years old. Aging is an important risk factor for sudden cardiac death. From 1 to 13 years, only one in five sudden natural deaths is due to cardiac causes. Between 14 and 21 years old, the proportion increases to 30%, and then to 88% for middle-aged and elderly people. Young and middle-aged men and women have different susceptibilities to SCD, but the gender difference disappears with advancing age. The total male/female ratio is approximately 4:1, but in the 45-64 age group, SCD in men increases and the ratio is almost 7:1. This percentage drops to 2:1 between 65 and 74 years old (2, 3).

The difference in SCD risk parallels the risk for other manifestations of coronary heart disease in men and women. There are also differences by race, with the incidence of SCD being higher in Caucasian men than non-Caucasian men for the 55-64 and 65-74 age groups (2-4).

If we were to systematize the production mechanisms of SCDs, which are otherwise very complex, we can talk about 2 types of anomalies: pre-existing cardiac structural anomalies that form in the vulnerable substrate and transient functional factors that can transform a long-term, clinically latent structural anomaly , in a manifesto.

We are also talking about factors that are associated with an increased risk of SCD: advanced age, male sex, black race, family history of ICD, elevated LDL-cholesterol, hypertension, smoking, diabetes, increased heart rate, increased heart rate variability, excessive alcohol consumption, ECG/echo signs of LVH. Risk categories are described: Severe left ventricle (LV) dysfunction (LVEF below 35%), ischemic heart disease, history of AMI, history of malignant ventricular rhythm disorders.

In recent years, there has been discussion about the intervention of the genetic factor constituting what we call - The genetic bases of SCD, which are incriminated in a series of syndromes such as long QT syndrome, Brugada syndrome, obstructive-hypertrophic cardiomyopathy, arrhythmogenic right ventricle dysplasia, catecholaminergic polymorphic ventricular tachycardia , certain types of dilated cardiomyopathy. "The family environment, including dietary, psychological and developmental factors" may play a particular role in determining this aggregated susceptibility in family members. "Rare" variant of DNA, one or more polymorphisms (variants common DNA) (5).

"*Death stops both love and fights. Everyone remains only with how much he loved or how much he fought. He still has time, maybe, just to regret that he didn't love and fight enough..." (Octavian Paler)*

COLORECTAL CANCER: IT'S TIME TO A CALL FOR ACTION AMONG YOUNG ADULTS

Currently, colorectal cancer (CRC) is the fourth most prevalent malignancy in both genders in United States of America, with approximately 150,000 new cases identified each year. However, over the past four decades, the overall incidence rate of CRC has considerably decreased (1, 2). Colonoscopy, the primary screening method for CRC, enables the identification and removal of colon polyps before they become malignant. The incidence rates of CRC in persons over 50 years have mostly been attributed to interrupting the adenoma-carcinoma sequence (3). Malignant colorectal malignancies could be found and removed at an early stage, together with the removal of the polyps, to reduce colorectal cancer mortality, by reducing the occurrence of precancerous lesions that would otherwise turn into cancer. In fact, studies using flexible sigmoidoscopy (18-26% in intention-to-screen analyses and 31-35% in per-protocol analyses, in RCTs), colonoscopy (68% in a meta-analysis of observational studies), and fecal immunochemical tests (10-22% in observational studies) have also shown decreased colorectal cancer incidence (4). In contrast, the prevalence of CRC in young patients has been progressively rising every year. In the past ten years, patients with CRC who were diagnosed while they were under 50 years old have formed the young-onset or early-onset CRC patient cohort. The term "young-onset" or "early-onset" colorectal cancer (CRC) refers to CRC that appears in individuals under 50 years who, until recently, did not meet the typical age criteria for average risk screening in the United States (3). This is concerning for a number of reasons. Firstly, this patient group is not routinely examined for colorectal cancer (CRC), as the conventional suggestion is for CRC screening to begin at age 50. Secondly, as we have learned over the past ten years, the concern extends beyond a delay in diagnosis and considers if there are several genetic and environmental factors that distinguish this group of young CRC patients (5).

When CRC incidence was examined using epidemiological data from 1974 to 2013, it was discovered that adults aged 20 to 39 had an annual increase in incidence of 2.4%, while adults aged 40 to 49 had an annual rise in incidence of 1.3% in the mid-1990s. There was a 3.3% yearly drop in the incidence rates of CRC in people over 65 between 2012 and 2016. During the same time period, the incidence rate of CRC among patients under 50 increased by 2.2% year, with people between the ages of 20 and 34 experiencing the largest increases (6). The second most common type of cancer in men under 50, and the fourth most common in women, is CRC at the moment. Recent estimates indicate that by 2030, the incidence rates of rectal and colon cancer in this population will both increase by 124.2% and 90%, respectively. Rectal cancer incidence rates have increased annually by 2.3% in adults aged 40 to 49 over the 1990s and by 3.2% in people aged 20 to 39 when compared to proximal colon cancer incidence rates. In patients under the age of 50, approximately 1 in 10 cases of colon cancer and 1 in

4 cases of rectal cancer are predicted to be diagnosed by 2030 (7). Despite a decline in CRC mortality rates among older persons, an estimated 1.9 deaths per 100000 people were projected to have occurred in 2018. Several countries, including Canada, United Kingdom, Sweden, Switzerland, Italy, Australia, Egypt, and Asia, have all documented international tendencies that are similar to the aforementioned USA trends (2, 8).

There are significant racial and ethnic differences in the incidence of CRC in the United States (5). Wallace *et al.* reported that in contrast to 8.6% of non-Hispanic whites and Japanese, 21% of South Asians and 20% of Southeast Asians were diagnosed with colorectal cancer (CRC) before to the age of 50. The study examined patterns in the most racially and culturally diverse country's CRC frequency. When they were diagnosed, two thirds of those under 50 had a late-stage illness (regional or distant). Additionally, the research found that non-Hispanic Black Americans had lower overall survival rates and a higher than expected frequency of CRC diagnosis (9). When it came to late-stage sickness, non-Hispanic black Americans had a 40% higher prevalence than non-Hispanic white Americans. Between 1990 and 2014, South-East Asian communities saw a rise in the incidence of colorectal cancer, in contrast to the general population (10).

The biggest identified risk factor for the disease is a family history of CRC. There was a family history of CRC in 23–39% of patients with young-onset CRC, according to estimates. There is a two- to four-fold increased risk of having CRC in those with first-degree relatives who have the condition, and this risk increases with younger age at diagnosis (11). CRC risk is increased by having numerous affected first-degree and distant relatives with an adenoma's family history (12). Globally, the incidence of CRC in young adults has increased, which is assumed to be due to a major birth cohort impact, which effects occur when age-specific incidence rates vary by age group as a result of a change in exposure to variables (behavioral, cultural, lifestyle, and environmental variables that affect disease risk) (13). A typical "Western" diet, which is high in fast food, processed meat, and red meat, as well as a lack of exercise and consumption of fruits and vegetables, is linked to an elevated risk of CRC (1). The screening level of CRC risk was achieved 5 years faster in diabetic patients than in a 50-year-old man or woman without diabetes, according to a national longitudinal study including 12.6 million Swedish inhabitants between 1964 and 2015. This result enabled researchers to estimate how much faster patients with diabetes would develop the 10-year cumulative risk of CRC than a 50-year-old man or woman without diabetes (14).

According to a study by Glover *et al.*, patients with colorectal cancer (CRC) who were between the ages of 20 and 39 had higher rates of medical comorbidities, such as diabetes, obesity, or smoking, and the greater prevalence of malignant lesions in youth may or may not be caused by behavioral variables (15). The risk of CRC is also increased by a factor of two to three by inflammatory bowel disease (IBD), and the likelihood of APC mutations is lower in young-onset CRC patients with IBD and higher in those with mucinous or signet ring histology (16).

Caucasian women are more likely than black women to develop CRC at an early age. Although colorectal cancer (CRC) usually has no symptoms, there are warning signs that could include changes in stool

diameter, unexplained anemia, and rectal bleeding. The most common initial signs of CRC with a young onset include rectal bleeding/hematochezia, altered bowel habits, stomach discomfort, anemia, decreased appetite, and weight loss. Per the research, the diagnosis of colorectal cancer (CRC) is postponed in those under 50 years of age by seven weeks to two years. Clinicians who treat or refer patients for anorectal evaluation (e.g., hemorrhoids) or who think the condition is benign, similar to irritable bowel syndrome, may have a low degree of suspicion for colorectal cancer (17). Often, younger-onset colorectal cancers (CRCs) originate away from the rectum or splenic flexure and are less likely to have a prior adenomatous lesion (11). Younger people with colorectal cancer also seems to be diagnosed with synchronous or metachronous malignancies more frequently than older patients with colorectal cancer, and they also appear to be diagnosed at a later stage (presenting with distant or regional metastases) (16).

The American Cancer Society announced recommendations for CRC screening for persons at average risk starting at age 45 in May 2018 (18). Moreover, other Americans oncological societies most recently increased its recommendations for CRC screening standards to encompass individuals between ages 45-49. In additions they advise starting screening for persons who have a family history of CRC 10 years before the youngest affected relative is diagnosed with the disease or at age 40, whichever comes first (5). In European countries, the implementation of screening programs begins around age of 50 or above, since older persons are more likely to get colorectal cancer, a population screening program for those under 50 years old may not be practical (19). Moreover, a recent study published by Cardoso *et al*. found that nations with long-standing screening programs and coverage of more than 50% of the eligible population saw significant decreases in colorectal cancer incidence. In nations with no screening programs in place, incidence rates were either steady or gradually rising (4).

It has been shown that young people with CRC experience a delay in diagnosis and are identified at later stages of the disease. Clinicians must keep a close eye out for the warning signs of CRC, as well as any family history and genetic abnormalities, in order to effectively assess, identify, and treat CRC in young adults. Therefore, population-based studies are required to both examine the significance of conventional risk factors in young-onset CRC and to find lifestyle and environmental factors linked to the disease. Finding the fraction of young people who might benefit from colorectal screening while minimizing the cost burden on society is the challenge of the future.

ANTIBIOTIC RESISTANCE: A NEW RISING SILENT PANDEMIC

Antimicrobial resistance (AMR) poses a significant global public health threat, ranking in the top 10 challenges faced by humanity. The primary factors contributing to the emergence of antimicrobial resistance in pathogenic bacteria are the inappropriate usage and excessive use of antimicrobials, which leads to the proliferation of drug-resistant infections. Inadequate infection control, clean water, and sanitation deficiencies exacerbate the establishment and dissemination of AMR bacteria (1). The presence of antibiotic resistance results in extended hospital stays, increased death rates, and a substantial financial burden. The presence of resistant bacteria has hindered our capacity to effectively address novel and emerging infections. The rate at which microorganisms develop resistance mechanisms is affected by the excessive usage and incorrect use of antibiotics, in addition to their natural acquisition of resistance (2).

While antibiotics are widespread substances, it is unlikely that environmental bacteria, commensals, and human and animal diseases will encounter the same varieties of antibiotics. Pathogenic bacteria are more likely to encounter therapeutic doses of antibiotics that are of medical significance. In their study, Darmancier *et al.* conducted a thorough bioinformatic analysis of 16,632 full bacterial reference genome sequences. The objective was to determine if there is a correlation between bacterial virulence and antibiotic resistance. They discovered data indicating that certain types of genes related to disease severity and resistance to antibiotics could be simultaneously favored and that mobile genetic components, such as integrative and conjugative elements, could have a significant role in facilitating their transfer. The emergence of antibiotic resistance in human infections, which necessitates specialized medications for treatment, has become a significant barrier to effectively treating diseases that pose a hazard to humans (3). This collection compiles papers on antibiotic resistance in several significant emerging infectious pathogens, including *Mycobacteroides* abscessus, *Klebsiella pneumoniae*, *Salmonella sp*., *Francisella tularensis*, *Acinetobacter baumannii*, and *Pseudomonas aeruginosa*. It also covers antibiotic resistance in other human pathogens such as *Neisseria gonorrheae*, *Staphylococcus aureus*, and *Escherichia coli*. Most of these diseases are classified as high priority by the National Institute of Allergy and Infectious Diseases, and they are considered internationally and medically significant (4).

Despite continuous endeavors to reduce the excessive utilization of antibiotic treatments, the prescription of antibiotics remains unavoidable, particularly in severe instances such as bacterial co-infections or secondary infections accompanying another illness, to guarantee the complete eradication of the pathogen load. Lower- and upper-respiratory tract viral infections greatly increase the likelihood of bacterial infections in patients. This is due to several factors: the viruses create more opportunities for bacteria to attach to surfaces, they weaken the immune system's ability to respond, and they cause damage to cells and tissues, which makes it easier for bacteria to spread and cause severe infection (5, 6).

Secondary bacterial infections, such as those caused by *Streptococcus pneumoniae*, *Streptococcus pyogenes*, *S. aureus*, and *Haemophilus influenzae*, can further exacerbate viral disorders. It should be emphasized that bacterial co-infections are less common than secondary infections (7). Out of a sample size of approximately 1,400 individuals with COVID-19, Wang *et al.* found that 2.7% of individuals were identified as having a concurrent bacterial infection with the viral illness (8). Another study by Chen *et al.* described that 5.1% of the cases (5 out of 99) of COVID-19 had co-infections, namely involving *Acinetobacter baumannii* and *Klebsiella pneumoniae* (9). In a comprehensive study conducted by Blasco *et al.*, involving a total of 221 patients diagnosed with COVID-19, it was shown that 25.8% of these patients (57 out of 221) had co-infections. Furthermore, among these co-infected cases, 29.8% were specifically identified as having bacterial co-infections (10). Therefore, there has been a rise in the occurrence of hospital-acquired infections and sepsis during the COVID-19 pandemic, highlighting the significance of readily available testing and diagnostics for both co-infections and secondary infections. However, the availability of such testing has been restricted during the pandemic. An important obstacle lies in the inconsistent rate of diagnosed co-infections and secondary infections, which highlights the lack of effective diagnostics for these illnesses. This is particularly evident in the absence of rapid identification of bacteria and resistances, even when hospitals are under strain or testing is required in settings with limited resources (11).

Although antibiotic treatments have proven to be effective, the heightened utilization of antibiotics in COVID-19 hospitalizations during this pandemic is expected to exert significant selective pressure on bacterial pathogens, prompting them to develop resistance. Consequently, there will likely be a rise in the occurrence of drug-resistant bacterial infections (12). The bacterial infections reported in COVID-19 patients consist of Streptococcus pneumoniae, *Klebsiella pneumoniae*, *Haemophilus influenzae*, *Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Acinetobacter baumannii*. According to the Center for Disease Control and Prevention of the United States of America, these diseases are also among the most common and life-threatening cases of antibiotic resistance (13).

Engineering assays that promptly differentiate between viral and bacterial infections would reduce the wasteful use of antibiotics by preventing their preemptive prescription. This is in addition to the development of diagnostics for microbial pathogens. Traditional diagnostic techniques for bacterial infections include genotypic methods that identify resistance genes or immunological assays like ELISA (enzyme-linked immunosorbent assay) that rely on interactions between antigens and antibodies. A significant limitation of conventional methods is their time-consuming nature and the need for centralized laboratory facilities (14). In addition, genotypic approaches cannot identify antimicrobial susceptibility and growing resistance patterns in cases where a specific gene has not been identified. Biosensing technologies have shown considerable promise in enabling fast point-of-care testing using affordable devices (15).

The articles in this special edition concentrate on newly identified and recurring infections, as well as the antimicrobial resistance (AMR) linked to them. From our perspective, comprehending AMR and its present progression is of the highest priority. The discoveries in these publications could additionally aid in the advancement of diag-

nostics, therapeutics, and prevention measures to control and alleviate the risks posed by infectious diseases, while also ensuring the sustainability and safety of food and the environment. We anticipate that these publications will help and provoke thought among readers engaged in the topic of antimicrobial resistance (AMR).

THE MEMORY OF PROFESSOR VALERIU RUSU, M.D., Ph.D., GUIDING LIGHT IN THE DEVELOPMENT OF NUCLEAR IMAGING DOMAIN: TEN YEARS OF A FULFILLED LEGACY IN THE FIELD OF NUCLEAR MEDICINE AT IASI

It has already passed, as if in an instant, ten years since the premature disappearance of the distinguished Professor Valeriu Rusu M.D., Ph.D., the mentor of nuclear medicine in Iasi. Many things remain encrypted in his mind, an unwritten encyclopedia, which gone, unfortunately, with the being. But there are also many essential things that have remained here, with us, through the school he formed around him.

The master's words are our legacy: *"I have other projects, also, but their completion does not depend only on me... I don't know if time will be patient".* And even if time ran out of patience, unfairly quickly, the teacher's words turned into a duty of honor for the collaborators he trained, professionally and morally, and the Professor's projects were and are being carried forward, developed and successfully completed.

The Nuclear Medicine Laboratory *"Professor Valeriu Rusu, M.D., Ph.D.*" currently bears his name and keeps his memory alive. It could not have been otherwise, because it was developed and formed by the great professor to be the place where, from the whole country, all SPECT vector molecules imported into Romania are always used the most and the newest techniques in the field of nuclear imaging are introduced, for the final benefit of the patient.

It was a difficult 10 years period for the laboratory which initially, through the immense effort of the Professor, was equipped with two SPECT gamma camera devices, innovative for the endowment years, 1990-2000, which allowed it to develop important projects and publications in the field, at a level that quickly brought the Iasi university center to first place in the country in the field of functional imaging research, devices that, obviously, would wear out physically and morally in over 20 years. There followed memos upon memos, attempts, often unsuccessful, repeated with the perseverance learned from the mentor, so that, in the end, they were successful in renewing the equipment to world standards.

The laboratory has developed and, today, is equipped, as a result of a project co-financed from the European Regional Development Fund through the Competitiveness Operational Program 2014-2020, with the only SPECT-CT gamma camera in our university center and one of the 2 in Moldova; along with a SPECT gamma camera, maintained with seriousness and care by the laboratory staff, as the teacher taught us, currently used for Pediatric Nephrology - the center being the only one in the country where the use of functional imaging for the benefit of pediatric nephrology pathology is developed at international standards. Within the laboratory, the first center in the country was established, which aims to use artificial intelligence for the benefit of precision medicine, starting from imaging data, MEDIMAG IA (Regional Center of Excel-

lence for Personalized Diagnosis and Artificial Intelligence in Medicine and Imaging), which creates the premises for international collaborations that will contribute both to increasing the visibility of our university and of region, for the final benefit of the patient.

These are standards that keep nuclear medicine from our university center where our master taught us that it should be: a spearhead in fundamental and applied research in the field of nuclear imaging in our country and in understanding images through biophysical uptake mechanisms of radiopharmaceuticals, according to the French model - the most logical model, France being the country where the professor completed his professional training, through the famous governmental scholarship, Bourse de Collège de Médecine des Hôpitaux de Paris, and where he, later, guided the steps of 3 collaborators, 2 of them currently continuing in the field, demonstrating care for the formation of a school of nuclear medicine that will continue the development of the field, in Iasi. It remains, even currently, the laboratory with the most teaching staff in the field, in the country and one of the only 2 centers in the country that coordinate doctoral studies.

As a result of all these arguments, starting from the foundations created by the Professor and through the openness that the "Grigore T. Popa" University of Medicine and Pharmacy from Iasi and the "Sf. Spiridon" County Clinical Emergency Hospital had in encouraging this action, Iasi is currently the only university center where functional imaging is the nucleus around which the only cluster dedicated to medical imaging in the country has developed, the IMAGO-MOL Cluster, which militates, together with University and through the collaboration of over 70 members (universities, research institutes, private members), for increasing the visibility of nuclear imaging in synchronism with artificial intelligence, through European projects and publications in prestigious journals, and through international collaborations, starting with student exchanges from the most distant countries (such as Brazil, Mexico or Japan), through involvement in international scientific consortia.

We would not have succeeded in fulfilling this duty of honor, regarding the endowment at world standards, in one year, as long as the project lasted, if we had not learned from our mentor the seriousness of a job well done, tenacity and perseverance doubled by professionalism, teamwork based on communication and mutual respect, surrounded in a formative way by young specialists, students, residents, PhD students in the domain, the openness to collaboration with the applied fields of nuclear imaging and, perhaps most importantly, the professional enthusiast.... all representing the legacy of the soul that the Professor left us.

The same legacy can be found in another field dear to the Master – *"The Medical-Surgical Journal of the Society of Doctors and Naturalists from Iasi"*, the oldest medical society in South-Eastern Europe. It is the place where Professor Valeriu Rusu was the Editor in Chief, for 20 years (1994-2014), of the first medical journal in Romania (1833), marking, for sure, in a positively determining way, the development of the journal. Here, the periodic meetings of the Editorial Board represented, at the same time, real lessons in critical medical reading, particularly valuable for the young part of the Editorial staff; it is also the place that has often been a silent witness to some tasty discus-

sions full of intellectual contortionism between great masters from the medical world, discussion partners of the master, discussions watched with looks full of professional enthusiasm by the other members of the collective.

The brilliance achieved by the fields he touched explains, without a doubt, what was so special in the personality of Professor Valeriu Rusu, what attracted and conquered the hundreds of students who filled his amphitheaters and all those who knew him, from where the "aura" of the so respected and beloved teacher came from.

All of them were the expression of his personality: an erudite, an encyclopedic mind that managed to give sparkle to the fields he developed, positively marking their evolution even beyond passing into non-existence. Seriousness + extreme self-demand = Professionalism, to which the teacher gave color through professional enthusiasm developed in a philosophically erudite manner, this was his essence, which he managed to induce to those he mentored, also. Because, above all, the teacher remains a great lover of the profession of educator and trainer of the minds of the many students, Ph.D. students and young specialists whom he mentored.

A righteous teacher, who was only sometimes, influenced by his own heart, a teacher who managed to find the way to the misunderstood part of each of his students, chiseling, sometimes demandingly, but always with exceptional results, their skills for medical research.

Even if time ran out of patience and the Professor left us too soon, he will remain alive in our memory, of those he guided and mentored and of all those who knew him, and through the fulfillment of the projects he had. Our mentor's projects have become the moral duty that we always try to carry out and to develop in an innovative and formative way, for those who will follow and, always, for the final benefit of the patient.

At every step, the teacher's words and memory remained our guiding light.

He looks at us from the painting on the wall of the Nuclear Medicine Laboratory, and seems to be smiling slightly, we hope satisfied with what has been achieved so far, but, as if also a bit admonitory, to take care to tirelessly continue the development of nuclear imaging, of the laboratory whose value he cherished and shepherded her all his life and of all other fields that he loved so much.

*Professor **Cipriana Ştefănescu**, M.D., Ph.D.,*

LIVER TRANSPLANTATION: WHERE ARE WE?

Modern surgery was born in the second half of the 19th century, with the introduction of general anesthesia. Gradually, surgeons began to become more and more daring, performing operations that were not possible until then. In this context, at the beginning of the 20th century, the old dream of medicine was revived, that of completely replacing organs whose function was destroyed, with healthy ones.

The decisive step was taken by the great scientist Alexis Carrell, laureate of the Nobel Prize for medicine in 1912, who described the technique of vascular anastomoses (as it is easy to imagine, the new organ is connected to the receptor using such anastomoses).

From this moment begins a spectacular race that contributed to a huge extent to the progress of medicine in general, allowing not only the development of surgery at an unprecedented level, but also of other specialties such as anesthesia and intensive care, immunology, infectious diseases and not in lastly, internal medicine specialties such as nephrology, cardiology, hepatology, pneumology, etc.

The driving force of this race, which today is in full swing, were the surgeons, the ones who stubbornly demonstrated that the operations to replace irremediably compromised organs can be performed.

The operation was not the biggest problem in the case of the kidney, which was the first organ successfully transplanted in December 1954 at the Peter Bent Brigham Hospital in Boston by Joseph Murray and his team (the surgeon being rewarded with the Nobel Prize in 1991). Instead, at least at the beginning, it seemed that in the case of the liver, the technical problems are so great that there were opinions that the operation to replace this organ with the survival of the patient will never be possible.

At the beginning there were two great surgeons who tried to contradict these opinions: Thomas Starzl in Denver and Francis Moore in Boston (the same place where the first kidney transplant had been performed). Both surgeons performed the first liver transplant operations in the first half of 1963, but none of the transplanted patients survived. It seemed that the pessimists would be right! Nevertheless, Francis Moore was selected by Time magazine as the most important personality of that year and made the already famous cover.

Meanwhile, anesthesia and intensive care had made remarkable progress, which had considerably increased the chances of success of the operations.

On the other hand, advances in immunology allowed the identification of the phenomenon of "rejection", set up against the transplanted organ by the recipient's immune system which recognizes the new organ as "non-self".

The first therapeutic protocols for the control of rejection, based on cortisone and azathioprine (Imuran), had limited success and it was obvious that something more efficient would be necessary.

After four years in which none of the transplanted patients survived postoperatively, in 1967 Thomas Starzl obtained the great victory: the first liver transplantation with patient survival!

At the end of the 1960s, an ad hoc

Committee (including besides doctors and ethicists as well as a priest) from Harvard University sets up the criteria for declaring "brain death", which regulated organ donation from people whose brain was irreversibly destroyed.

The 60s saw moments of enthusiasm for xenotransplantation, the transplantation from an animal (chimpanzee or baboon) to a human, but the immunological barrier proved very strong and the method was abandoned until more effective immunosuppression protocols were found.

The real success of the liver transplant occurred only after 1980, the year in which Ciclosporin was introduced. This was a powerful and effective immunosuppressive drug discovered by chance in a sample of Norwegian soil by Jean Borel in the laboratories of the Sandoz company and tested in the clinic by the great surgeon and pioneer of liver transplantation in England, Roy Calne, at Cambridge University.

Also, in the 80s, the Belzer solution (or UW-University of Wisconsin solution) was discovered, which replaced the old Collins solution (with the later version Euro-Collins) and allowed the preservation of the liver outside the body for up to 12 hours.

Since 1983, liver transplantation has become an accepted therapeutic method. Pittsburgh, the city where Thomas Starzl had moved with his team, became the world capital of transplantation, a position it would remain until the early 1990s. In Europe, successful programs were built by Roy Calne at the University of Cambridge, Henri Bismuth at the Paul Brousse Hospital in Paris and Rudolf Pichlmayr at the Hanover University Hospital.

In 1989, Christoph Broelsch initiates the first successful program in Chicago with a liver fragment from an adult (usually one of the parents) to a child. After 1990, Asian surgeons (Masatoshi Makuuchi and Kyoichi Tanaka in Japan, ST Fan in Hong Kong) introduced liver transplantation from adult to adult, usually using the right hemified (whose volume represents about 65% of the liver volume).

At the beginning of the 1990s, Thomas Starzl successfully tests Tacrolimus, an immunosuppressant more effective than Ciclosporin. Using the new medicine, in 1992 he performed two xenotransplants from baboon to man, but the two patients did not survive and the method was again abandoned for a while. The main conclusion was that the two calcineurin inhibitors (Cyclosporin and Tacrolimus) effectively control acute rejection (mediated by T lymphocytes), but do not control hyperacute rejection (mediated by antibodies).

Liver transplantation was making remarkable progress based on the two types of donors: those who are "brain dead" and "living" donors (parents or relatives).

Transplantation with a fragment of liver solves pediatric patients to a great extent, especially after, thanks to Rudolf Pichlmayr and Henri Bismuth, it is proven that a fragment of liver can also be obtained by dividing the entire liver from a brain-dead donor (in which case segments 2 and 3 are transplanted to a child, and the rest of the liver, i.e. segments 1,4,5, 6, 7 and 8, to an adult). Together, the living donor (mother or father) and the split liver, covered completely most waiting lists in pediatric programs.

The living donor liver transplantation was more difficult to implement in adults, due to the risks to the donor (right hepatectomy being an operation that registered an estimated mortality of 1-1.5% in the 90s).

That's why it succeeded primarily in Asia and less so in Europe and the USA, where the legal problems in the case of donor death even led to the closure of some

transplant programs. Among the Asian programs for liver transplantation from a living donor, the greatest success was SG Lee's program from Seoul (University Center "Asan"), where the so-called dual transplantation was also introduced: when a single fragment of liver was not enough (this fragment must represent between 0.8 and 1% of the recipient's body weight), two donors were used, from which two liver fragments were taken and implanted into a single recipient.

As the experience of the transplant teams increased, the indications of liver transplantation were better defined:

- In children: biliary atresia and metabolic diseases
- In adults: Cirrhosis in terminal stages (after infection with virus B or C, alcoholic, biliary, autoimmune and, more recently, through the evolution of hepatic steatosis), acute liver failure (poisoning with poisonous mushrooms or with drugs such as paracetamol), cancer (hepatocarcinoma in the first place) and metabolic diseases (Wilson's disease, amyloidosis)

At the end of the 1990s, a new category of donors was introduced, those in so-called "circulatory death", i.e. donors with cardiac arrest who did not respond to resuscitation maneuvers but from whom, if the harvesting is done very quickly, the organs can be used for transplantation.

In Romania, liver transplantation was introduced at the "Fundeni" Clinical Institute. The first four operations (performed between 1997-1999) did not result in the survival of the patients. The first two liver transplants with survival took place in 2000 (April 15th for patient Gheorghe Penea and, respectively, May 5th for patient Gheorghe Badea), with a liver from a brain-dead donor. Currently both are alive and in very good health, 24 years after the transplant.

A very short time later, the liver transplant from a living donor was introduced (with a fragment of liver from the mother to little Timeea Balogh, aged one year at the time of the transplant). Currently, Timeea is a university graduate and mother of a 2-year-old boy.

Later, liver transplantation from a living donor to an adult was introduced, with the help of the team from the University of Essen (Christoph Broelsch, Massimo Malago).

Although the number of donors was initially reduced, the number of operations increased from year to year, reaching a maximum in 2013, with 122 liver transplant operations. It was also the year in which Professor Vladimir Hotineanu's team, partially trained at the "Fundeni" Clinical Institute, inaugurated the transplant program from the Republic of Moldova at the Republican Hospital in Chisinau. In 2014, the second transplant program was inaugurated in Bucharest, at the "Sf. Maria" Clinical Hospital in Iasi, and in 2016, the liver transplant program started at the "Sf. Spiridon" Clinical Hospital in Iasi. Finally, in 2021, the first transplants from a living donor were performed at the "Sanador" Hospital in Bucharest and the pediatric transplant program at the "Grigore Alexandrescu" Children's Hospital started (joint program with the one at the "Fundeni" Clinical Institute, where both the harvesting from the living adult donor and the splitting of the liver, in the case of split liver transplantation, are performed).

The main liver transplant program remains the one at the "Fundeni" Clinical Institute, where the range of types of operations gradually diversified, being carried out in addition to whole liver transplantation from a brain-dead donor other procedure like split liver transplantation (for an adult

and a child or for two adults), transplant from living donor to child and adult, with one or even two liver fragments (dual transplant), domino transplant.

Since 2016, the perfusion of the liver outside the body using the Liver Assist infusion machine has been introduced. The main indication of this method remains the liver from marginal donors (elderly donors, with resuscitated cardiac arrest, staying in intensive care for many days, requiring high doses of vasopressors or with a significant degree of steatosis, etc.) in which there is a risk of not function in the recipient's body ("primary non-function", a situation that requires urgent retransplantation).

Nowadays in such cases the marginal liver is installed on the machine and perfused for at least two hours, during which the aspect of the organ is monitored, the perfusion pressures in the portal vein and in the hepatic artery are evaluated and the transaminases in the perfusion liquid are measured.

After the introduction of this method, the percentage of non-primary liver functions was practically reduced to zero.

Another advance of modern surgery introduced in the program at the "Fundeni" Clinical Institute was the laparoscopic surgery for the harvesting of the liver fragment from the adult in the pediatric transplant. This first step can continue with the use of the method for the harvesting of the right hemi liver in the case of transplantation from an adult donor, an operation that is already performed in the US and Western Europe (where robotic surgery is increasingly used as an alternative to laparoscopic surgery).

The beginning of 2024 saw a revival of xenotransplantation at the international level. If in the past "donors" were chosen from primate species (chimpanzee, baboon), considered to be the closest to humans from a genetic point of view (and therefore the least exposed to rejection), nowadays there is a different approach. Advances in genetic engineering have led to the possibility of modifying the genome of animals in those places responsible for the synthesis of the blood components involved in hyperacute rejection (those that make up "the complement system"). Through the method called CRISPR (clustered regularly interspaced short palindromic repeats) - Cas9 (a protein that allows binding to the targeted DNA sequence) certain genes can be "cut out" and removed or, if necessary, replaced with others, depending on what you need. This method was considered as potentially capable of creating transgenic animals whose organs could be transplanted into humans

The animal on which the research is now focused is the pig, because its organs are very close in anatomy and function to human ones; in addition, the pig grows quickly and multiplies at a rate that allows obtaining as many organs as needed (unlike primates which, if they had proven to be suitable as organ donors for humans, would have risked disappearing very quickly as species).

The suppressed gene ("knock-out") is N-galactosyl transferase, which is involved in the synthesis of the complement system.

The American company eGenesis has managed to produce genetically modified transgenic pigs on an industrial scale so that their organs can be transplanted into humans. Starting from 2021, and especially at the beginning of 2024, several kidney, heart and liver transplants were performed in different centers in the United States. Although the initial evolution was favorable and no case of hyperacute rejection was registered, the transplanted patients did not survive in the long term, dying at intervals of weeks or months after the transplant.

Research does not stop here, however. It is hoped that, in the not too distant future, genetic engineering will obtain the "ideal" animal, whose organs can be successfully transplanted into humans. When this objective is reached, the biggest problem of organ transplantation will be solved: the insufficient number of donors compared to the large number of patients registered on the waiting lists! At that moment, each patient will be able to receive the organ he needs at the right time.

Moreover, if we are allowed to dream, this organ could be genetically modified in such a way that it is recognized as SELF by the body of the recipient. In this situation, the rejection reaction will no longer be triggered and, therefore, there will be no need for postoperative immunosuppression (which is now necessary for the rest of life in transplanted patients). It will be the moment when the golden dream of all transplantologists, IMMUNE TOLERANCE, will become reality!

ON AN ANNIVERSARY – 145 YEARS OF HIGHER MEDICAL EDUCATION IN IAŞI

From the country's first University to the Medical-Pharmaceutical University of Iași

In his conference "The past and present status of Iași", held in the University Hall of the City on November 29, 1931, Professor Grigore T. Popa, with a remarkable and visionary sense of reality, tells a truth that, even today, should disturb simple people, academics or politicians, remaining a constant reminder: "A first-rank University in Iași means placing Iași at the forefront of Romanian culture. A decayed University in Iași means the exit of this city from the determinant factors of national culture". Fortunately, the first option has proved viable until today. The University of Iași opened on the 26th of October, 1860, and was the first modern one in the United Principalities of Moldavia and Wallachia. Within this University, the Faculty of Medicine could be inaugurated only in 1879, 1st of December. It was the result of harmonious collaboration between the Administration (*Epitropia*) of "Sf. Spiridon" Hospitals, the Society of Physicians and Naturalists (SMN), and the Michaelian Academy. The first two establishments spatially delineated a sacred equilateral triangle with the "Gate of Hope" of the University Palace included in this area, a truth that is impossible not to make people think of a deeper meaning.

Starting as a modest Faculty of Medicine of the Iași University, in 1879, it witnessed an incredible transformation, growing into an autonomous University of Medicine and Pharmacy, including four Faculties and several Colleges, bearing Professor Grigore T. Popa's name, as its most outstanding personality. Since 1999, the bust of the skilled anatomist and humanist philosopher Grigore T. Popa keeps guarding the esplanade of the Nation Square in front of the University, with the Great Union Monument, where today, among others, medicine and pharmacy students, teachers and friends walk, talk and enjoy this recreational and emotional space. Now, in 2024, on the 145th anniversary of the Medical Faculty and present day "Grigore T. Popa" University of Medicine and Pharmacy from Iasi, we can affirm without error that the institution we serve with devotion and humility, as our brilliant predecessors did, aspired and succeeded in living up to the ideals animating the 19th century Romanian intellectuals who strove for national emancipation and for developing their own high schools and universities.

In 1873, in the House of Commons, the British prime minister Benjamin Disraeli synthetically expressed his conviction that: "A University should be a place of light, freedom and learning". Who else better than Grigore T. Popa exemplified, in Iași and in Romania, this ideal through all his activity and academic endeavor? In Iași – said Grigore T. Popa, former student and then professor of this institution – "the University has to promote science, the basis of human renewal" and a constant "reform of the spirit" for the better, thus turning into the center of enlightened knowledge and creativity.

Semper Altius! The prerequisites of Higher Medical Education in Iași

On October 26th 1860, Mihail Kogălniceanu, Prince Alexandru I. Cuza's minister of Public Instruction and Cults, claimed that: "...undoubtedly, the country needs lawyers, philosophers, doctors of justice and doctors of wisdom, but the country also needs doctors of the body, physicians". In his turn, in the session of September 16, 1860, Dr. Iacob Czihac, member of the Schools Council, read the program of the Faculty of Medicine, the Ministry of Public Instruction adopted under no. 10.976, but things could not be finalized. In fact, medical education in Iași had gained experience and already had a certain tradition. Training centers existed at least since 1757, when the establishment of the "Sf. Spiridon" Hospital, the basis of future university clinics, was officially inaugurated. In 1838, at a Congress of Naturalists in Freiburg im Breisgau, Dr. Czihac, one of the founders of the Iași Society of Physicians and Naturalists (SMN, 1830), mentioned, in his report on the education in the Principality of Moldavia, the intention to initiate a "course of surgery" in Iași. In 1842, Dr. Gheorghe Cuciureanu, one of Moldavia's protomedics and SMN's presidents, proposed the organization and functioning of a Faculty of Medicine within the "St. Spyridon" Hospital Establishments. Due to several visionary forerunners nurturing brilliant ideas, the SMN in Iași, founded in 1830, was the first modern European-type scientific society in the Romanian Countries and even in Southeast Europe. It introduced the scientific spirit to the Romanian Principalities and was the first structure to develop higher education in Romanian language, promoting the first local national academic institutions: the Michaelian Academy (1835), the University of Iași (1860) - the first in the United Principalities of Moldavia and Wallachia (1860)-, and, only later, the Faculty of Medicine (1879). On January 1st, 1887 SMN started editing the first medical journal of a Romanian academic society, the "Bulletin of the Society of Physicians and Naturalists in Iași", renamed, in 1924, "The Medical-Surgical Journal. Bulletin of the Society of Physicians and Naturalists in Iași", in order to emphasize its medical character. Printed in Romanian and in French, the journal represented the best way of scientific visibility and elevate valorization, at a European level, of the activity of the teaching staff of the young University and some of its Faculties, medicine included. Little by little it remained the forum of the Faculty of Medicine alone. Surviving until nowadays, "The Medical-Surgical Journal"/ Bulletin of the Society of Physicians and Naturalists of Iași" is a generalist periodical, appearing exclusively in English since 2012. In 2024 it reached 128 publishing years, and is on the Clarivate Analytics list, with a 0.1 impact factor in 2023. SMN motto "*Semper altius" - Always Higher* is coming more and more true, indeed.

In 1852, supported by Moldavia's Ruling Prince, Grigore Alexandru Ghica, and Moldavia's protomedic, Dr. Gh.Cuciureanu, Dr. Anastasie Fatu organised and then directed the "Gregorian Institute"- "Obstrical Art Institute" – a sort of Maternity Hospital, which integrated the first midwifery school in Moldavia, core of the future obstetric clinic. Between 1857-1859, under protomedic Ludwig Steege's mandate, Moldavian Pharmacists Guild opened a School for Pharmacy Technicians in Iași, preparing qualified personnel. By the end of 1859, Dr. Nicolae Negura, supported by Prince Alexandru I. Cuza, officially initiated, in the premises of the Michaelian Academy, a

short-lived course of surgery and pharmacy, another attempt to behind medical education in Iași and Moldavia (Moldova). However, a Faculty of Medicine could be born only almost two decades after the University of Iași was established, in 1879, and then, not as a medal awarded to Iași medicine for its contribution to the Romanian War of Independence (1877-1878), but as a contract-commitment for healing the war wounds. The courses began on December 1, 1879, when Dr. Leon Sculy held the first anatomy lesson in the headquarter of the Iași University, where the Medical Faculty owned two rooms. The former headquarter is today's administrative Palace of the University of Medicine and Pharmacy. This is how our Faculty history started, with only 14 students and two professors, Sculy Logothetidis – a skilled surgeon teaching anatomy and histology, and the renowned scientist, Petru Poni, member of the Romanian Academy, who taught chemistry, heading the Chemistry Department of the Faculty of Science. The Medical Faculty's clinical base was generously offered by "Sf. Spiridon" Hospital Administration in Iași. The beginnings of our Faculty were modest, the endowment precarious. But eventually won the desire of some enthusiasts to show the country, and those who did not believe it, that, overcoming all difficulties, Iași can assert itself in the field of medicine and pharmacy, hence in science, and not only in the field of art and culture.

The rise of the Faculty

A most significant case: The Faculty of Medicine in Iaşi entered Europe, right from its birth; it was born both in Iași and in Europe through the teachers trained in France, Germany, Austria, or Italy, integrating, from the first moment, the medical scientific spirit of Europe, here, at our home. The incomparable initiators of Romanian medical education, Leon Sculy - the first Dean of the Faculty -, Ludovic Russ senior, Aristide Peride, Ludovic Russ junior, Constantin Botez, Emanoil Riegler, Theodosie Philipescu, Gabriel Socor, Vasile Bejan, George Bogdan, Francisc Rainer, Elena Densusianu Pușcariu and others, due to their hard work and rich experience, through the suffering inherent in any struggle, placed, from its very beginning, the medical school of Iași at European and international levels. Besides, at the Iași University, lady doctors were more easily accepted and even promoted right from the dawn of the 20th century. Dr. Elena Puscariu, the first female physician to become a university professor in her country and, probably, the first woman professor of ophthalmology in the world, is just an example. Owing to the disciples of these groundbreaking professors, graduates from the young Faculty of Iași, like Ion Tănăsescu, Alexandru Brăescu, or Alexandru Moruzi, the medical school in Iași imposed itself with authority in the field of surgery, and nervous pathology, for instance. Even though the Faculty of Medicine started with 14 students, their number gradually increased up, in only 20 years, to 100 at the end of the 19th century. The number of students amplified significantly after the inauguration of the Institute of Anatomy in 1894, a building considered at that time the most modern of its kind in Southeast Europe. Today, after 130 years, this edifice, emblem of our University, renovated from the ground up, is one of the constructions that Iași is proud of. In 1912, the first wing of the new Faculty building, surrounding the central Palace, was put into use, and in 1932, the second wing. From five university clinics in 1900, it reached 21 in 1938; from

2,030 volumes existing in the library at the end of the 19th century, it reached about 22,000 in 1939. In 1913, a section of Pharmaceutical Education began to function within the University of Iași, associated to the Faculty of Medicine. In 1934, Pharmaceutical Education was concentrated in the Bucharest Faculty of Pharmacy alone; consequently, the other sections in the country ceased to exist.

Due to the great prestige acquired in the country and abroad, the Faculty's role increased substantially after the Great Union of Romania achieved in the 1st of December 1918, date after which it received students from all the Romanian provinces reunited with their mother country, but mainly from Bessarabia and Bucovina, historical parts of Moldova itself. Thus, between the two World Wars, the enrollment figure was of 1,388 students. Also during this golden interwar period of the Faculty, great personalities of Romanian medicine and culture were trained in this Faculty, such as Eugen I. Mironescu - professor of dermatology clinic, writer and important collaborator of the *"Viaţa Românească"* magazine, Gheorghe Tudoranu - professor of pathology, medical clinic and hematology, and an essayist as well, the talented publicist and writer Grigore T. Popa, the patron of our University, the one who discovered the portal pituitary system, pioneering neuroendocrinology, an acknowledged personality of both the Romanian and international academic life, man of culture - cofounder and collaborator of *"Însemnări Ieşene"*, a heroic civic spirit. Close to the students and the sick, they represented respected and loved human and professional role models and were refined persons of elevated culture.

After five decades of existence, the Faculty of Medicine in Iași was imposing itself through its high scientific and cultural tradition, through the founders of modern schools in all the disciplines and their prominent followers: Constantin Ionescu-Mihaiesti, Alexandru Slatineanu and Mihai Ciuca – bacteriology; Nicolae Leon – parasitology; Alexandru Tupa – histology and histopathology; Vasile Rascanu – physiology; Jules Nitulescu – pathophysiology; Constantin I. Parhon – neurology, endocrinology and gerontology he initially named *iliki-biology* (gr. *ηλικι:age* – age biology); Ernest Juvara, Ion Tanasescu, Nicolae Hortolomei, Vladimir Butureanu, Georghe Chipail – surgery; Oscar Franche – urology; Theodor Economu – orthopedics; Gheorghe Demetriade, Eugen I. Mironescu, Gheorghe Nastase – dermatology; Maria Franche – infectious diseases; Constantin Bacaloglu, Ion Enescu – medical clinic and cardiology; Leon Ballif – psychiatry; Emil Radu – radiology; Eugen Aburel, Gheorghe Placinteanu, Vasile Dobrovici – obstetrics and gynecology; Dumitru Cornelson – hygiene. These names are few, indeed, compared with the large number of graduates and professors who illustrated Romanian medicine. We must also mention other personalities trained on the benches of this Faculty and at the bedsides of Iași Hospitals, of whom the University has always been proud: Ion Gr. Nubert and Ion Iancu - professors of anatomy, Petre Condrea – bacteriology and inframicrobiology (virology); Constantin C. Dimitriu - medical clinic and semiology; Gheorghe Popovici – pharmacology; Maria Briese – endocrinology; Zoe Caraman – neurology; Maria Sibi – Biochemistry; Gheorghe Timosca, Mircea Rusu – stomatology, oral and maxillofacial surgery; Marcel Kapri, Traian Baran, followed by Valeriu Rusu - medical physics, renamed medical biophysics in 1948 and completed with nuclear medicine since 1963; Ion Hăulica – physiology; Carol

Stanciu – internal medicine, gastroenterology and hepatology; Eugen Târcoveanu – laparoscopic surgery; Ostin Costel Mungiu – pharmacology; Mircea Covic – genetics; Marcel Burlea - pediatrics are just a few examples. All these fields were integrated to medical education, practice and research.

From a Faculty to a complex University

In 1948, as a result of the education reform, the Faculty was transformed into the Institute of Medicine, later called Institute of Medicine and Pharmacy, which included several Faculties: General Medicine, Pediatrics, Hygiene, Pharmacy and Stomatology (Dental Medicine). Between 1956-1960, everything is concentrated in the Institute of Medicine with a single Faculty of Medicine possessing two sections: The General Medicine section and the Pediatrics section. In 1960, the Dentistry Section was re-established, and in 1961, the Pharmacy one, functioning as such until 1965, led by the dean of the Faculty of Medicine. In 1965, the Institute of Medicine changed its structure again, becoming the Institute of Medicine and Pharmacy (IMF), with three faculties, with their own deans, namely: 1.the Faculty of Medicine, integrating the Section of General Medicine and the Section of Pediatrics; 2.the Faculty of Stomatology (today: Dental Medicine); 3. the Faculty of Pharmacy.

Many of those who graduated after 1961-1970 established themselves in the Iași medical center, practicing as university teachers, heads of departments and prestigious medical practitioners in the healthcare network, illustrating the new Faculties and specialties integrated into the Institute and their rapid development.

The contribution of Iași University students over time to the progress of research and general medico-pharmaceutical activity, both in other centers of the country and abroad, should also be remembered. In the country, the creation of the Faculty of Medicine in Timişoara in 1945 was supported for a short time, by Professor Emil Hurmuzache, a reputed pediatrician from Professor Manicatide's school, followed by the future Professor Louis Turcanu; currently, the Pediatric Hospital in the Timisoara bears the latter's name; Professor Vladimir Busila helped the Department and Clinic of infectious diseases; Professor Dumitru (Luchi) Popescu developed obstetrics-gynecology, while Professor Constantin Zosin and Dr. Paula (Paulette) Zosin, illustrating Professor Ion Enescu's school, were efficiently involved in promoting internal medicine and nephrology. Equally in Timisoara, Dental Medicine benefited from Professor Nicolae Dutescu's expertise. Professor Maria Cernea, instructed with Professor Vasile Dobrovici in obstetrics-gynecology, and Professor Paul Cernea, a skilled ophthalmologist from Professor Petre Vancea's Clinic, contributed to the consolidation of the Faculty of Medicine in Craiova. In the same way, the Faculty of Medicine in Constanta has integrated teaching staff specialized in Iaşi, such as Professor Iuliana Dimofte – genetics and Professor Petru Bordei – anatomy. From Professor Ion Enescu's school of cardiology, the future professors Samuel and Olga Zoneraich established themselves in the USA where they had a successful career. In the meantime, such examples have greatly multiplied, not only in Romania, but also on an international level.

One hundred years after the founding of the school of higher medical education in Iași, in 1979, under communist rigors, the Institute of Medicine and Pharmacy Centenary was celebrated, an event with nation-

al and international participation, mainly from communist countries, which allowed to bring to attention the guiding lines of Iași medicine, its personalities, including that of Grigore T. Popa, to pay tribute to the pioneers and the tradition of this academic medical institution, so that its flame was passed on to younger generations. The first two out of the four volumes of scientific works of the event reviewed the great predecessors and the history of the departments, completing the album and the other iatrohistorical and medico-pharmaceutical syntheses edited on that very occasion. In 1979, the Iași Institute of Medicine and Pharmacy was training 3,354 students, of which 795 were students from other countries, had 450 members in the teaching staff, 46 laboratories and 38 university clinics, and a Center (Institute) for the Improvement and Specialization of Physicians and Pharmacists (IPSM). During the communist period, the University had professors of great standing, trained in the interwar period, who continued the founders' tradition, even though under undeniable threats and constraints: Ion Iancu, Vladimir Bușureanu, Alla Vâță, Petre Vancea, Martian Cotrău, Nicolae Bălan. The successful tradition went on due to several other representatives of Iași medical education: Gheorghe Chișleag, Mihai Duca, Constantin Negoiță, Petre Brânzei, Nicolae Costinescu, Emil Hurmuzache, Virgil Costea, Grigore Teodorovici, Ernest Ungureanu, Nicolae Bumbăcescu, Ioan Selmiciu, Emanoil Grigorescu, Constantin Strat, Marcel Burdea, Asia Chipail, Gheorghe Ghimicescu, Nicolae Oblu, Gheorghe Bădărau, Costache Lazăr, Mircea Chifan, Victor Strat, Gheorghe Scripcaru and others.

In 1991, our institution was transformed into the University of Medicine and Pharmacy. Since 1994 it bears the name of the reputed Professor Grigore T. Popa (1892-1948), who graduated from the Iași Faculty of Medicine. The medical school in Iași was also revived when, in 1994, to the three previous Faculties, the only Medical Bioengineering Faculty in the country was added, which brilliantly upgraded the spectrum of training for leading specialists in contemporary, highly computerized medical practice and (bio)technologies. This accomplishment owes its existence to Professor Florin Topoliceanu's dedication and visionary perseverance. Colleges, focused on complementary specializations, were in turn created over time: Dental Technique (1993), Dental Assistance and Prophylaxis, Medical Assistance, Nutrition and Dietetics, Audiology and Hearing Prosthetics, Balneophysiokinesiotherapy (Physical Therapy) and Rehabilitation (1999), Medical cosmetics and cosmetic product technology.

Over the years other numerous research centers or institutes appeared or were technically upgraded keeping pace with contemporary medical and scientific practice, not only in Romania, but also abroad: the Center for Gastroenterology and Hepatology, the Institute of Cardiology, the Institute of Psychiatry, the Endocrinology Center, Nephrology and Renal Dialysis Clinics, Center for laparoscopic surgery, Organ donation and harvesting center, Kidney transplant and Liver transplant clinics, an Algesiology center for the study of pain, together with the more classical laboratories for Radio imaging, Interventional radiology, and Nuclear medicine, an Excellence Center for Experimental Medicine (CEMEX); besides a Center for Modern Languages and Cultural Integration was set up too.

The university clinics were equipped, the educational spaces and the Central Library were updated, the dormitories for students

and residents were renovated and modernized, major repairs and consolidations were carried out in the old University buildings, which today have an elegant aspect. Students benefit from the most modern and probably the tallest educational edifice in Iași - the "Nicolae Leon" Building (Ghica-Vodă St.) - and the most modern and equipped Simulation Center (M. Kogălniceanu St.), a 7 million euros investment, bearing the name of Prof. Cristian Dragomir, a well-known surgeon in Iași. Almost all teachers specialized equally abroad; our participation in international scientific events, grants and projects substantially increased, inter-university exchanges significantly augmented from the Freiburg Program to the Bologna Project, from the Socrates Program to the Erasmus and Erasmus Plus Mobilities.

The myth of the Iași medical school is therefore a reality, it has been reshaped and regenerated in a modern academic spirit. The influx of young people and their and interest in applying for admission to the "Grigore T. Popa" University in Iași is far from a mere coincidence, since our graduates rank among the first in the residency examinations and contests.

The number of students and teaching staff continually increased. If in the academic year 2002-2003 there were 5,319 students, guided by 950 teaching staff members, in 2014, the University trained 8,687 students, of which 2,570 were students from other countries, 2,192 residents, 265 master's students and 344 doctoral students. A particular success was recorded by the French-language series. In 2019, the "Grigore T. Popa" University of Medicine and Pharmacy had four faculties and four university colleges: The Faculty of Medicine, the Faculty of Dental Medicine, the Faculty of Pharmacy, the Faculty of Medical Bioengineering, the only one in Romania since 1994. Today, with a teaching staff of 900 members, UMF prepares approximately 12,000 students in 7 specialties, 4 of which in a new field - unique in the country for the time being: medical bioengineering. Given the need for continuous training, distance education has also been implemented. University medical practice and clinical research are carried out in the 55 specialized clinics organized in 12 university clinical hospitals, in 2 university polyclinics, in the unique Cardiology Center in Moldova, as well as in the Dialysis Center. On September 5, 2017, "Grigore T. Popa" U.M.Ph. became the first medical higher education institution in Romania listed in the Times Higher Education World University Rankings. In terms of the international academic visibility indicator, U.M.Ph. in Iași ranked first in the country and in the top 500 universities in the world (428th place).

If in the decades before 1989 at the Institute of Medicine and Pharmacy in Iași, foreign students learned the Romanian language in order to complete their medical and pharmaceutical studies alongside their Romanian colleagues at the Faculty of Medicine, in the academic year 1991-1992, a first line of study was opened entirely in English, which doubled in 2013-2014. In the 2009-2010 academic year, a first line of full medical study was inaugurated in French. Since 2013-2014, two French-speaking lines, with about 75 places each, are available to students at the Iași Faculty of Medicine. Since 2009-2010, sections in foreign languages have been also introduced to the Faculty of Dental Medicine – English and French - and the Faculty of Pharmacy – English. Presently the Faculty of Medical Bioengineering – Physical Therapy and Rehabilitation Specialization equally provides undergraduate

studies and master's degree courses in English. Master degree are also released by the Faculty of Medical Bioengineering. At the end of 2014, a University Success Center *(Centre de Réussite Universitaire - CRU*) was inaugurated with the support of the Francophonie University Agency *(Agence Universitaire de la Francophonie - AUF)* - Office for Central and Eastern Europe. Presently the number of foreign students at "Grigore T. Popa" U.M.Ph. from Iași is estimated to 2,600, situating the University on the first place in Romania among similar institutions. Undoubtedly, the students' influx and their desire to enroll in the column of the "Grigore T. Popa" University in Iași is not just a happy happening.

Projects for a "Medical University City"

In 2024, after 145 years of development, we are enjoying a period of stability and constant progress: in the last 8 years, the "Nicolae Leon" building was inaugurated hosting 6 modern lecture rooms with over 700 seats (a real congress center), and a center for fundamental medical skills. The "Grigore T. Popa" University Conferences program has opened, where scientific and cultural personalities from the country and abroad are invited; the Seniors' Club (Sf. Athanasie St.) was organized along with the "I. I. Mironescu" Cultural Center; in April 2024, the "Confucius" Institute (Gh. Sîulescu St.) was inaugurated; an IT platform has been achieved for monitoring the didactic process and exams; works are in progress for the consolidation, rehabilitation and modernization of the Dentistry Polyclinic for Adults located in the Craftsmen's Insurance House (Casa de Asigurări a Meseriașilor), in its 'Vault' *(Bolta),* in front of the "Sf. Spiridon" Hospital, and offering to the Faculty of Dental Medicine modern spaces for clinical practice and students' training; the same is true for the Children's Dentistry Polyclinic (Al. Lapusneanu St.), which will provide the Faculty of Dental Medicine with spaces for clinical education and practice, equipped with state-of-the-art equipment; the former "Prof. Dumitru Bagdasar" canteen will be transformed into a modern sports center, a gym for physical education activities and for student sports competitions (Sărărie St.); the consolidation, rehabilitation and modernization of the Sports Hall - the former "1st of December" canteen is another objective to fulfill along with the renovation and modernization of the University campus infrastructure (C9 and C10 dormitories) which will improve accommodation conditions for students; the renovation of the Anatomy Institute is carried out together with the consolidation and rehabilitation of "Prof. Vladimir Bușureanu" House; the consolidation, rehabilitation and conversion of the attic room of the "1st of May" A - Student Residence; the construction of a multifunctional building, also housing a library, is part of the ongoing projects of the University which equally include a Center for Fundamental Research, consisting of an integrated platform for interdisciplinary and transdisciplinary studies, endowed with the necessary specific infrastructure allowing molecular biology, genetics, immunology analyses and so on; a Maternal-Fetal Research Center for investigations focused on the maternal-fetal health is envisaged as well; a translational medicine research center is being built close to the U.M.Ph: it is the TRANSCEND Research Center, designed to promote and consolidate excellence in interdisciplinary biomedical research; located in the Regional Institute of Oncology Iași (RIO/IRO), a "smart" hospital, TRANSCEND is financed from the

European Structural Fund; concurrently IRO develops robotic surgery using the Da Vinci Robot and aims at upgrading medical practice, education and research; recently has started the construction of the new Regional Emergency Hospital in Iași, another smart university establishment; solar panels systems for producing sustainable energy has been parallelly considered by these up-to-date strategies.

That is why in June 2024, "Grigore T. Popa" University of Medicine and Pharmacy borrowed 35.4 million euros from the European Investment Bank (EIB) through EIB's public sector loans for Central and South-Eastern Europe – intended for the rehabilitation and modernization of the University campus buildings. This transaction represents the first external loan University made and the first EIB operation within a 200-million-euro initiative meant to improve higher education in Romania. The loan granted by the EIB to the University of Medicine and Pharmacy in Iași aims at supporting renovation, modernization and (re)construction of University buildings. The University itself will invest over 70 million euros. This is the sixth agreement of the EIB with a Romanian University. A prosperous University like U.M.Ph. Iași needed such an agreement with a major international bank like EIB, enabling major investment projects. Otherwise, as the Rector pointed out, "due to legislation, Romanian Universities have no financial autonomy, and the possibility of accessing one's own funds is reduced".

Art, philosophy, cultural competence and medical humanities should eventually render higher education in this University more prone to personalized medicine and empathy, respectful of ethics and deontology applied in everyday life practice and at the patient's bedside. In accordance with this approach the International Festival of Poetry held in Iași, in May 2024, for instance, was hosted by the Museum of Medical History of our University.

"Gr. T. Popa" Publishing House developed, with over 100 books being printed annually.

The U.M.Ph. Central Medical Library has two locations (V. Alecsandri St. and in "N. Leon" Building, Ghica-Vodă St.) with several modern reading rooms; it has over 470,000 volumes, computerized materials, and ensures access to online information; it possesses specialized libraries in almost every department or discipline, 28 laboratories, IT documentation rooms; it has the Liberty online platform with 24/7 free access and an E-learning platform; it provides access to the books of the biggest medical publishing houses, access and subscriptions to most important medical journals in the world and offers students and teaching staff the possibility of consulting the latest specialty publications.

As part of its continuing medical education program, the Iași University of Medicine and Pharmacy organizes improvement and advanced specialization courses (238 proposed courses, attended by over 2415 physicians and pharmacists); it trains residents in all specialties acknowledged by the Ministry of Health (3,453 physicians, 90 from other countries). UMF includes an excellent Doctoral School, which attracts an impressive number of young people, their number constantly increasing in the fields of medicine, dentistry and pharmacy. The University has 109 doctoral supervisors, 598 doctoral students; the Doctoral School initiated 66 research projects won through national or international competitions in the last 6 years, during which time 153 doctoral theses were finished, all confirmed by CNATCDU (Na-

tional Council for the Attestation of University Titles, Diplomas and Certificates). Currently U.M.Ph. has 4 faculties, 926 teaching staff, 9,908 students, representing 75 nations, 3,947 resident physicians, 508 Ph.D. students, 359 master students and 12,697 places available in educational spaces. National and international projects enrich the University's activity maintaining it in the international scientific network.

The precious treasure of our University is the ALUMNI community, the 139 promotions of graduated physicians, along with all the pharmacists, dentists and medical bioengineers graduated from the same Alma Mater, present here, in Romania, or anywhere else in the world from Europe to the USA, Australia or Japan, have proven the nobility of the medical profession and allied sciences, and have competently cared for suffering people. Thus, they became the best ambassadors of Iași and Romania in the world.

Always a "Gate of Hope"- an Arch of Triumph

The University of Medicine and Pharmacy teaching staff always included outstanding personalities, corresponding and full members of the Romanian Academy, such as Grigore T. Popa himself (corresponding member, 1936), members of the Romanian Academy of Medical Sciences and of the Scientists' Academy of Romania. Since the 2020s "Grigore T. Popa" University awarded Doctor Honoris Causa degrees to remarkable national and international leading figures in their specialties and professions. Some of them were former students who graduated from this very Alma Mater who in the meantime gain fame in their own country or abroad. In their turn, valuable personalities of the "Grigore T. Popa" University were rewarded by similar honorary distinctions bestowed on them by Romanian and foreign Universities. Consequently, stronger cooperation relationships continue to successfully develop enabling medical and pharmaceutical education to flourish in Iași and in the whole country. In fact, after the 1990, UMF could rewire its activity to European and other global scientific networks, forging complementary opportunities for its own present and future.

Committed to scientific and ethical principles, the Masters of the Faculty founded in 1879, of the Institute of Medicine and Pharmacy established in 1948, and redimensioned as a University of Medicine and Pharmacy in 1991 - have truly and tenaciously sculpted their being, character and scientific personality in light, elevation and sacrifice, as in Elektra's myth, reigniting the column torch that enlightens us. As Professor Grigore T. Popa said, "elastic horizons must be left to the soul, which have with them the expected mirage of long distances, for which the misfortunes of the moment can be endured." The mirage worked out for our University, too. The "Gate of Hope", archway of the first modern University founded in Romania – presently "Al. I. Cuza" University -, is today the triumphal arch of our new University of Medicine and Pharmacy. Even if the Faculty of Medicine could not pass triumphantly under it on October 26th 1860, when the old pioneering institution came into being, today nothing prevents the inscription on its vault of the names of those who served, with faith and dedication, the art of medicine and medical education in Iași. The column we are evoking, under the circumstances of the 145 year anniversary of higher medical education in Iași, seems to be an endless column, like the one imagined and made by the unsurpassed Romanian sculptor Constantin Brâncuși; it

seems a humanized column comparable to the Ecorche -"the skinned man"- preserved in our Institute of Anatomy Museum, made by the same Brancusi, in which the human body perfect morphology is seen and felt as an eternal resurrection promise.

George Emil Palade and the Iași University of Medicine and Pharmacy

2024 marks 150 years since the birth of Professor Constantin I. Parhon (1874-1969), dean of our Medical Faculty (1923-1926), member of the Romanian Academy (1939), one of the founders of Romanian and international endocrinology and gerontology, specialties he promoted within the Socola School of neurology and mental diseases, he created in Iași (1912-1933). More than this, 2024 is equally the year when Romania and Iași celebrate Professor George Emil Palade, the scientist born in Iași on November 19, 1912, who in 1974, received the only medical Nobel Prize awarded to a Romanian, so far. G. E. Palade (1912-2008) honored Iași and its University of Medicine and Pharmacy by accepting the title of Doctor Honoris Causa, which this institution conferred on him on the 30th of May 1994, in the lecture hall now bearing his name. Reputed representatives of the Iași University of Medicine and Pharmacy were among those due to whom Palade received the same honorary distinction on behalf of the Romanian Scientists' Academy in 1994, as well. Palade always remembered his two master anatomists from Iași, he met, as a student, at the Faculty of Medicine in Bucharest: his doctoral thesis supervisor, Professor Francisc Rainer, and his young collaborator, Dr. Grigore T. Popa. Years later, in 1944-1945, Popa, from whom Palade confessed that he learned the accuracy of laboratory experiments, advised and helped him to pursue in-depth studies abroad. Indeed, once he arrived in the USA, Palade's glorious scientific destiny could be efficiently fulfilled. Palade welcomed in his Laboratory in the USA Romanian specialists and skilled researchers among whom some came from Iași. Tightly attached to his mother land, he constantly tried to support and encourage promising Romanian scientists. His presence in Iași and in our University certainly stimulated and ennobled us with a glow of his Nobel Prize and he still does.

Passing the flame

Crowning its 140 activity and endeavor for excellence in medical education, and still remembering the centenary of Greater Romania (1918-2018), the Royal Family of Romania offered "Grigore T. Popa" University the *Nihil Sine Deo* decoration for the important part it played in fostering a rich exchange of opinions and expertise on the latest advancements in medical bioengineering and medicine, as a whole. It is the only medical University in Romania to have won this award. In 2019, on its 140th anniversary, the country's President rewarded "Grigore T. Popa" University with the "Order of Merit for Education" in the rank of Grand Officer "for the exceptional results obtained in intellectual and human training of young generations, as well as in the process of scientific research, standing out as a model of excellence in Romanian higher education and contributing, in this way, to raising the prestige of local and national communities".

This memory recall occurs now because the need for gratitude tears is simply felt, without any sadness of the balance sheet, but also without festive explosions, trying to make it fit the pure truth which a destiny and a myth could arise from. On the 1st of December 2024, 145 years are celebrated

since the birth of the higher medical school in Iași. Remembering its evolution, we are more than convinced that we can be happy and proud to pass over the abys of time the flame of knowledge and cutting-edge science our forerunners enthusiastically once lit, promoting health and education, combating ignorance and disease. We are thankful and honored to belong to this community - a perennial belonging together of mind and soul to our Alma Mater.

Vivat Academia! Semper Altius!

Viorel Scripcariu, M.D., Ph.D.
Professor of Surgery
Rector of "Grigore Popa" University of Medicine and Pharmacy Iași
President of Romanian Society of Surgery,
President of the Society of Physicians and Naturalists of Iași

Dana Baran, M.D., Ph.D.
President-elect of the
International Society for the History of Medicine

Eugen Târcoveanu, M.D., Ph.D.
Professor of Surgery
"Grigore Popa" University of Medicine and Pharmacy Iași
Romanian Academy of Medical Sciences
First Vice-President of the Society of Physicians and Naturalists of Iași

EDITORIAL

ARTIFICIAL INTELLIGENCE IN SURGERY AND SURGICAL EDUCATION

Modern surgery has undergone an impressive evolution due to advancements in fundamental research, anesthesia, diagnostic tools, genetics, immunology, pharmacology, and especially artificial intelligence (AI). AI is defined as *"the study of computations that enable a machine to perceive, reason, and act."* In 1950, Alan Turing described intelligent behavior in computers as the ability to achieve human-level performance in cognitive tasks. Over the past 20 years, interest in AI in the medical field has significantly increased, leading to a true revolution and high expectations.

Modern medicine faces the challenge of acquiring, analyzing, and storing large amounts of information needed to solve complex clinical problems. The development of AI-based medical programs generally aims to formulate diagnoses, make therapeutic decisions, and predict outcomes. AI tools are designed to support the medical team in their daily tasks by processing data efficiently. This major progress has been made possible by the convergence of four key factors:

1. Large databases
2. Increased computing power
3. Deep learning algorithms, which have become the primary approach to creating intelligence at levels exceeding human capabilities, from image recognition to digital language processing
4. Significant investments

The cognitive revolution promised by AI has the potential to mitigate the shortage of doctors, particularly in fields like radiology and pathology, but it will not replace doctors in making therapeutic decisions.

Today, we can talk about **digital surgery (DS)**, which is shaping a global framework for surgical training, education, and planning. DS represents a milestone in computer-assisted surgery and the new era of automated surgery, robotic learning, and augmented environments. Digital surgery, which already exists (e.g., robotic surgery), leverages AI's power and connectivity as a crucial resource for the next generation of surgeons, particularly through machine learning on both regional and global scales.

As the **third revolution in surgery**, DS will help surgeons manage complex surgical environments, optimize team efficiency, and improve patient outcomes. It will enable healthcare teams to perform better, understand the needs of surgeons and surgical teams, and ultimately provide better patient care. Furthermore, DS will enhance hospital administration by offering a clear perspective on operating room activities, adjusting financial resources accordingly, and improving treatment efficiency while making surgical care more accessible worldwide.

By leveraging data, optimizing best practices, and refining surgical training, DS will ensure high-quality care, reduce outcome variability, and identify key factors that improve patient recovery. DS presents major opportunities, including enhanced surgical training through simulation, increased transparency in operating rooms, and the identification of factors influencing postoperative outcomes. It relies on robotic surgery, advanced instrumentation, improved visualization, connectivity, and data analysis. For DS to develop, it is essential to establish an infrastructure that seamlessly integrates robotics, AI, advanced surgical tools, and

educational programs to facilitate rapid innovation and surgical progress.

AI in Surgery: Enhancing, Not Replacing, the Human Element

AI is already integrated into all phases of surgery:

Preoperative phase: AI enhances preoperative planning by improving risk assessment and 3D modeling, allowing for better-informed decisions;

Intraoperative phase: AI aids in real-time image analysis and robotic assistance, increasing precision and minimizing complications;

Postoperative phase: AI predicts and detects complications early, personalizes recovery monitoring, and enables long-term patient follow-up.

With the rising number of surgical procedures, AI's role in surgery will continue to grow by improving precision, real-time diagnostics, customized surgical approaches, intraoperative navigation, risk prediction, and postoperative monitoring. AI has the potential to enhance patient outcomes, facilitate surgical education, and optimize surgical care.

AI supports surgeons in three main phases of their work:

1. **Preoperative planning**: AI can integrate population-level surgical data to determine patient-specific risks and expected outcomes, facilitating evidence-based treatment decisions. Deep learning techniques enable AI to recognize individual anatomical variations from medical images, helping surgeons anticipate intraoperative challenges. Sophisticated AI algorithms can process large imaging datasets to generate detailed 3D models of anatomical structures, offering interactive visualizations that enhance surgical field analysis.

2. **Intraoperative assistance**: AI-powered imaging techniques help surgeons identify anatomical structures with high precision and track instruments in real-time. AI systems assist in robotic surgeries by providing instant feedback and performing automated tasks. In colorectal cancer surgery, for instance, AI-powered tumor sensors ensure precise tumor resection, reducing positive surgical margins and improving oncological safety.

3. **Postoperative monitoring**: AI continues to assist patients beyond the operating room by enabling personalized and proactive post-surgical care. Intelligent algorithms track vital parameters, analyze data from various sources, and detect early signs of complications, allowing timely intervention. Wearable devices provide real-time recovery data, enabling healthcare teams to tailor rehabilitation plans and schedule follow-ups based on prognostic data.

From an **ethical** perspective, AI systems must undergo continuous monitoring to ensure patient safety and data privacy. Surgeons play a crucial role in decision-making with AI, requiring adequate training. As AI systems take on critical roles in healthcare-ranging from diagnostics to treatment recommendations and surgical tool control-it is vital to ensure that AI-driven decisions align with ethical standards and individual patient needs. While AI-assisted clinical decision support systems can provide precise recommendations, there is a risk of over-reliance on AI, which may lead to potential harm if AI recommendations are followed without considering patient-specific factors. Additionally, there is a concern that patient trust may erode if AI is perceived as the sole decision-maker.

AI and Surgical Education

The **benefits of AI in medical education** are numerous. AI-powered tools, such as ChatGPT, help doctors quickly and accurately respond to patient inquiries, offer personalized medical advice, and streamline administrative processes, improving patient

care efficiency. While some believe AI could replace doctors in the near future, this remains an illusion and an undesirable outcome.

One of AI's most crucial roles is in **surgical training**. The training process for surgical residents has evolved from the Halsted model (1890) of *"see one, do one, teach one"* to structured training programs.

The Rasmussen model (three-phase learning process) has proven effective:

1. **Skill-based behavior** – learning fundamental surgical gestures, understanding surgical instruments, aseptic techniques, and anatomical landmarks.

2. **Rule-based behavior** – mastering operative sequences, performing surgical procedures, and understanding surgical indications.

3. **Knowledge-based behavior** – acquiring the ability to handle critical situations, intraoperative complications, and complex surgical decisions.

The goal of surgical training is to develop professional competencies, assess theoretical knowledge, and enhance practical skills. The AI revolution is set to transform surgical education by introducing personalized, simulation-based learning experiences that redefine skill acquisition and refinement.

In **Romania**, the first **MIST-VR simulator** was introduced in Iași before 2000, significantly improving the surgical education. Today, "Grigore T. Popa" University of Medicine and Pharmacy of Iași hosts the most advanced simulation center in Romania, further enhancing surgical training. AI algorithms can assess trainees' strengths and weaknesses, tailoring training to their specific needs. AI's impact on surgical education extends beyond practice, as AI tools accelerate training by providing personalized learning experiences and objective skill assessments.

AI enhances simulation-based training by offering real-time feedback, objective evaluation tools, and tele-mentoring opportunities. AI algorithms can predict a trainee's performance and skill development, optimize training programs, facilitate communication, update curricula, and generate interactive content. Surgeons must understand AI's strengths and limitations, especially when transitioning from simulations to real-life surgeries. Future surgical training programs will incorporate AI-related knowledge and skills, requiring **multidisciplinary collaboration** among specialists to develop and implement AI in surgery.

The Ethical and Humanistic Perspective

Over **25 years of innovation**, AI models have matched human performance in certain aspects of patient care. However, this evolution has also raised challenges, including ethical dilemmas, data security concerns, and the need for appropriate regulations. Strategies for the **safe and effective integration of AI in surgery** include establishing robust safety protocols, conducting prospective clinical trials, training surgeons as AI end-users, and fostering interdisciplinary collaboration.

To **fully harness AI's potential**, continuous research, innovation, and collaboration are necessary to address technical, ethical, and organizational challenges. Aligning technological advances with patient-centered ethics and medical values will allow AI to elevate the standard of surgical care and improve outcomes worldwide. Addressing ethical, legal, and practical complexities-such as bias mitigation, patient privacy protection, AI system validation, and efficient integration into surgical practice and education-is crucial.

As some question whether **Hippocrates' Oath** remains relevant today, it is clear that this ethical code is more important than ever. Despite high-tech advancements and globalization, **the most vital aspect of sur-**

gery remains humanism and empathy-qualities no AI can replicate. If we lose this **divine gift of healing through human connection, we lose everything**, as François Rabelais once said: *"Science without conscience is the ruin of the soul."*

GLP-1 AND GIP REVOLUTION

Obesity is a chronic, relapsing, and multifaceted condition anticipated to impact around fifty percent of the United States population by 2030. Current estimates indicate that 650 million adults and 340 million children and adolescents (ages 5-19 y.o.) worldwide are affected by obesity (1). Alongside the markedly rising incidence, obesity carries substantial medical and economic consequences for both individuals and nations. Obesity costs the U.S. $480.7 billion in healthcare and an additional $1.24 trillion in lost economic output. Various therapies have been established to facilitate weight loss, including lifestyle modifications involving nutrition, with or without exercise and/or behavioral therapy, anti-obesity drugs (AOMs), endoscopic and surgical procedures. The most common AOMs, such as glucagon-like peptide-1 receptor agonist (GLP-1 RAs) and dual GLP-1 and glucose-dependent insulinotropic polypeptide receptor agonists (GLP-1/GIP RAs) have demonstrated substantial weight loss results and are gaining popularity as therapy choices. The Food and Drug Administration (FDA) approved the use of the GLP-1 receptor agonist Liraglutide for the management of overweight and obesity in 2014, followed by Semaglutide in 2021, and the combined GLP-1/GIP receptor agonist Tirzepatide in 2023 (3).

In recent years, the field of endocrinology has witnessed a transformative shift with the emergence of GLP-1 and GIP RAs. Originally developed as antidiabetic agents, these incretin-based therapies have evolved into multi-systemic modulators with powerful effects across cardiovascular, gastrointestinal, neurologic, and metabolic domains. The predominant side effects were gastrointestinal in nature, comprising nausea (40.2%), diarrhea (20.9%), constipation (20.0%), and vomiting (16.3%). Gastrointestinal adverse events resulted in drug cessation in 6.4% of individuals who were taking Liraglutide, in contrast to 0.7% in the placebo group (4). The incidence of side events for Semaglutide was comparable amongst participants in the treatment group (89.7%) and those in the placebo group (86.4%), regardless of causality. Comparable to liraglutide, gastrointestinal side effects (e.g., nausea, diarrhea, vomiting, and constipation) were recorded (74.2% of patients receiving Semaglutide). Most of these adverse effects were deemed mild to moderate and temporary, not necessitating the cessation of medication (5). Whereas more than two-third of the patients on placebo reported at least one adverse event, 78.9-81.8 percent of participants on Tirzepatide reported at least one adverse event, regardless of whether the adverse event was caused by the medication. In many negative events were also related to the digestive system. Furthermore, many of the adverse effects were temporary, ranging from mild to moderate in severity, and mostly manifested themselves during the period when the dose of Tirzepatide was being increased. Most adverse effects manifested themselves within the first eight to sixteen weeks of using the medicine (6).

In randomized controlled trials, the occurrence of serious adverse events was

notably higher in the liraglutide group (6.2%) compared to the placebo group (5.0%) (4). Participants who administered Semaglutide reported a higher incidence of serious adverse events (9.8%) compared to those receiving placebo (6.4%) (5). Additionally, 5.1-6.3% of participants administered Tirzepatide experienced serious adverse events, compared to 6.8% in the placebo group (6). A recent study employing a randomized sample of 16 million patients revealed that the use of liraglutide and Semaglutide, compared to bupropion-naltrexone, was linked to a heightened risk of pancreatitis, bowel obstruction, and gastroparesis, while no significant association was found with biliary disease (7). Moreover, the use of GLP-1Ras is associated with a significantly reduced quality of bowel preparation, resulting in an increased necessity for repeat colonoscopies. Enhancing pre-procedural planning for outpatient colonoscopies necessitates an understanding of the cumulative effects of medications that may hinder gastric emptying. This comprehension is crucial for identifying suitable interventions and counseling approaches (8).

The cardiovascular advantages of GLP-1 receptor agonists are now well-documented. Significant trials, including LEADER (liraglutide), SUSTAIN-6 (Semaglutide), and REWIND (dulaglutide), have shown reductions in major adverse cardiovascular events (MACE), notably non-fatal stroke and cardiovascular mortality. The observed effects seem to operate independently of glucose-lowering mechanisms and are likely facilitated by a combination of weight loss, anti-inflammatory actions, blood pressure reduction, and enhancements in endothelial function (9). Recent studies indicate that dual agonists such as Tirzepatide, which targets GIP and GLP-1 receptors, demonstrate enhanced efficacy in improving cardiometabolic markers; however, long-term cardiovascular outcome data remain under development (10).

Lipid and inflammatory cell deposits in the inner layer of large and medium-sized elastic and muscular arteries are the hallmarks of atherosclerosis, a chronic inflammatory disease. Diabetes mellitus, a pro-atherogenic factor that promotes the development of atherosclerosis and/or speeds up its progression through a multifactorial process, dramatically raises the risk of cardiovascular illnesses as well as overall cardiovascular mortality. In every study, GLP-1 receptors agonist, have demonstrated significant decreases in atherosclerotic events and all-cause mortality. According to preclinical research, GLP-1RAs influence several pathways involved in the formation and advancement of plaque, contributing to the immunomodulation of atherosclerosis (11). Although they both have positive effects on the cardiovascular system, statins and GLP-1 receptor agonists function differently and have various advantages in particular domains. Statins reduce the risk of heart attacks and strokes by lowering LDL cholesterol. Contrarily, GLP-1 receptors agonists have more extensive cardiovascular effects, such as lowering major adverse cardiovascular events (MACE), enhancing the prognosis of heart failure, and possibly even lowering limb events. They are becoming more widely acknowledged for their positive effects, especially in patients with type 2 diabetes and pre-existing cardiovascular disease, even though statins have a well-established function in primary and secondary prevention of cardiovascular disease (12).

GLP-1 receptors are present in various brain regions, such as the hypothalamus, hippocampus, and cortex, which are essential for regulating appetite, cognition, and mood. Research involving animals and

early human studies indicates neuroprotective functions in models of Alzheimer's disease, Parkinson's disease, and ischemic stroke. Current trials, such as EVOKE and EVOKE+, are evaluating the effects of Semaglutide on early Alzheimer's disease. Semaglutide may exert disease-modifying and neuroprotective influence in Alzheimer's through various mechanisms, including neuroinflammatory, vascular, and other processes associated with the disease (12).

The Liraglutide, Semaglutide, and Tirzepatide (15 mg) groups had higher rates of spontaneous hypoglycemia (1.3%, 0.6%, and 1.6%, respectively) compared to the placebo groups. These events were not regarded as serious. Hypoglycemia is a potential risk that must be considered when prescribing this medication to patients receiving insulin secretagogues or insulin, as indicated by prior research (3,13).

The incidence of benign and malignant neoplasms in the Liraglutide, Semaglutide, or Tirzepatide groups was comparable to that of the placebo group. No instances of medullary thyroid cancer or C-cell hyperplasia were reported in people assigned to the liraglutide, Semaglutide, or Tirzepatide groups. No clinically meaningful elevation in blood calcitonin levels is linked with the administration of these medicines (3). Notably, a greater number of female participants in the liraglutide group, compared to the placebo group, were diagnosed with malignant and premalignant breast neoplasms. Most of these patients exhibited above-average weight decrease (4).

One review included approximately 150 cases related to potential self-injury and suicidal ideation associated with liraglutide and Semaglutide, followed the reports of depression and suicidality. The causal relationship between the medications and these incidents remains uncertain; however, analogous issues have been documented with other AOMs. Liraglutide, Semaglutide, and Tirzepatide labels contain warnings regarding the need to monitor depression or suicidal ideation, whereas other GLP-1 receptor agonists do not include this warning. Most clinical trials for GLP-1RA have excluded individuals with a history of depression or suicidal behavior. The precise reasons for this exclusion remain unclear. Prescribing these drugs requires careful monitoring and caution, especially for individuals with a history of suicidality (14).

GLP-1 and GLP-1/GIP receptor agonists have shown significant weight loss results in clinical trials as well as in real-world data. Expert opinions highlight the necessity of meticulous patient selection, collaborative decision-making, and tailored dosing to achieve an optimal balance between benefits and risks. Continued research is essential to identify and mitigate potential side effects, including effects on gastric emptying and the necessity for precautionary measures during anesthesia. The increasing use of these medications necessitates evidence-based guidelines to ensure their safe and effective application in obesity management (3).

NON-INVASIVE VAGUS NERVE STIMULATION IN GASTROINTESTINAL DISORDERS

The vagus nerve, the primary component of the parasympathetic nervous system, plays a central role in regulating gastrointestinal sensitivity, motility, and immune responses (1). Composed of approximately 80% afferent and 20% efferent fibers, it serves as a critical communication pathway between the gut and the brain (2, 3). Afferent fibers transmit visceral information upwards from the gastrointestinal tract, including pain-related signals, thus participating actively in visceral nociception (4-6). Meanwhile, the efferent pathways influence parasympathetic preganglionic neurons in the dorsal motor nucleus and modulate sympathetic activity in the spinal cord, ultimately impacting gut motility and immune modulation (3).

This complex bidirectional network between the vagus nerve and the enteric nervous system forms the basis of the brain-gut axis, a fundamental mechanism for maintaining physiological homeostasis (1). In this context, stimulation of the vagus nerve, particularly through non-invasive transcutaneous auricular (taVNS) methods, is gaining attention for its potential therapeutic applications in gastrointestinal disorders.

Emerging evidence suggests that taVNS exerts meaningful effects across several physiological domains, including antinociception, anti-inflammation, improved motility, and restoration of intestinal barrier integrity. These mechanisms are particularly relevant in disorders marked by visceral hypersensitivity, such as irritable bowel syndrome and functional dyspepsia, now widely considered conditions of altered gut-brain interaction. Clinical studies have reported symptom relief and improved quality of life in affected individuals, reinforcing the therapeutic promise of neuromodulation in this field.

While current findings are encouraging, further investigation is needed to consolidate these observations into routine clinical practice. The modulation of vagal activity may well represent a turning point in the management of functional gastrointestinal disorders, one that addresses not just the symptoms, but the core physiological dysfunctions driving them.

The Therapeutic Potential of Vagus Nerve Stimulation in Gastrointestinal Disorders

Understanding the neurogastroenterological axis is essential in identifying innovative treatment strategies for functional and inflammatory gastrointestinal conditions. Among these, vagus nerve dysfunction has emerged as a critical pathophysiological component, especially in disorders characterized by gut-brain dysregulation and low-grade chronic inflammation (4).

Reduced vagal tone, a key marker of dysautonomia, has been consistently associated with conditions such as IBS and IBD (7, 8). Although findings related to autonomic imbalance in IBS remain somewhat inconsistent, often influenced by the predominant bowel habit subtype (9,10), the evidence suggests altered sympathetic-parasympathetic dynamics. Acute stress episodes typically provoke a sympathetic

surge, reflected in reduced heart rate variability (HRV), whereas chronic stress may perpetuate this imbalance, sustaining autonomic dysfunction over time (3,11,12). In IBS and IBD, this autonomic dysregulation often persists, potentially disrupting the brain-gut communication loop long term (13, 14).

More fundamentally, these autonomic alterations appear intertwined with dysregulation of the hypothalamic-pituitary-adrenal (HPA) axis, likely mediated by disrupted communication between key limbic structures such as the prefrontal cortex and amygdala, regions central to the central autonomic network (8). Vagal tone may thus serve as both a biomarker and a mediator of pathophysiology in these conditions (3, 15).

In light of these findings, the vagus nerve emerges not merely as a passive conduit but as a strategic target for therapeutic intervention. With its extensive innervation of the gastrointestinal tract and regulatory role in inflammation, pain modulation, and motility, VNS holds considerable promise as a non-pharmacological treatment option for gastrointestinal (GI) disorders involving gut-brain axis dysfunction (4).

Vagus Nerve Stimulation: From Concept to Clinical Potential

VNS works by delivering controlled electrical impulses to the vagus nerve, modulating both neural and immune pathways (1,16,17). It is broadly categorized into invasive and non-invasive modalities. The invasive approach, already established in epilepsy, involves surgical implantation of a pulse generator and electrodes on the cervical vagus nerve (4). While effective, it carries the risks associated with any surgical intervention.

By contrast, non-invasive approaches, particularly taVNS and transcutaneous cervical VNS (tcVNS), offer a less risky alternative. taVNS specifically targets the auricular branch of the vagus nerve through surface electrodes applied to the ear concha. Unlike tcVNS, which can stimulate both afferent and efferent fibers, taVNS is limited to afferent stimulation, yet still appears effective in modulating central autonomic circuits (1).

Beyond these, percutaneous electrical nerve field stimulation (PENFS) represents another minimally invasive modality. It applies needle-like electrodes to the ear's surface, activating cranial nerves including the vagus (V, VII, IX, X) and influencing the nucleus *tractus solitarii* (nTS), a major integration hub for vagal afferents (18).

Crucially, VNS may offer a therapeutic alternative to biological therapies, particularly in inflammatory GI conditions. While biologics have revolutionized disease control, their long-term use can be hampered by adverse effects and patient reluctance to continue treatment once remission is achieved (19-22). Non-adherence remains a significant concern, with rates reported as high to 50% (23). These challenges have led many patients to explore complementary options, with neuromodulation via VNS gaining increased attention (24).

VNS has emerged as a promising neuromodulator intervention for GI disorders, particularly those characterized by chronic abdominal pain, visceral hypersensitivity, and immune dysregulation, such as IBS, functional dyspepsia (FD), and IBD (1, 4). Vagal dysfunction, commonly reflected by reduced vagal tone, is frequently observed in these conditions and has been linked to autonomic imbalance and persistent gut-brain axis disruption (7-15).

Experimental and clinical studies suggest that VNS exerts dual antinociceptive and anti-inflammatory effects by modulat-

ing both central and peripheral pathways involved in pain and immune regulation (4, 25, 26). These mechanisms include activation of the cholinergic anti-inflammatory reflex via efferent vagal fibers and stimulation of the HPA axis via afferents (25-27). Furthermore, the vagal-splenic and vagal-sympathetic pathways have been implicated in suppressing proinflammatory cytokine release, particularly tumor necrosis factor-alpha, through β2-adrenergic and α7 nicotinic acetylcholine receptor signaling (17, 28, 29).

Non-invasive modalities such as taVNS and PENFS have demonstrated symptom relief in FD and IBS, improving gastric motility, reducing abdominal pain, and enhancing quality of life (10, 30-32). Clinical response rates with taVNS reached over 80% in some trials, with sustained benefits up to 12 weeks (32). In IBD, preliminary results indicate that taVNS may induce clinical remission and reduce disease activity scores, especially in pediatric populations (10, 33, 34).

While the variability in stimulation parameters (e.g., frequency, site, duration) may influence outcomes (35), current evidence supports VNS as a viable non-pharmacological therapy for functional and inflammatory GI disorders. Its capacity to regulate autonomic tone, suppress maladaptive inflammation, and improve visceral sensory processing underscores its therapeutic potential in disorders involving gut-brain interaction.

Although preliminary evidence is promising, non-invasive VNS requires further validation through large, standardized clinical trials. IBS may in fact be more of a stress-related disorder, and non-invasive therapies such as taVNS and PENFS offer a promising option for symptom management without major side effects (36). It is essential that researchers, clinicians, and policymakers collaborate to transform this technology from an experimental curiosity to a mainstay of gastroenterological therapy. Only in this way can we offer patients a safe, effective alternative without major side effects, paving the way for holistic management of digestive disorders.

EDITORIAL

RECURRENT RHABDOMYOLYSIS IN CHILDREN: A "RED FLAG" FOR UNDERLYING METABOLIC MYOPATHY AND THE NEED FOR NATIONAL PEDIATRIC VIGILANCE

Rhabdomyolysis is characterized by the rapid breakdown of skeletal muscle, resulting in the release of intracellular contents such as creatine kinase (CK), myoglobin, potassium, and phosphate into the circulation. This process can lead to acute kidney injury and metabolic disturbances (1).

In children, single episodes of rhabdomyolysis are usually secondary to infection, trauma, or strenuous exercise (2). However, recurrent rhabdomyolysis, defined as two or more distinct episodes, should raise suspicion for underlying metabolic myopathies, neuromuscular disorders, or genetic variants (3).

From a Romanian perspective, there are no reliable epidemiologic data on pediatric recurrent rhabdomyolysis. This gap is particularly significant given that approximately 75% of Romanian patients with rare diseases are children (4), suggesting that a notable subset may harbor unrecognized metabolic etiologies.

Pathophysiology and Triggers

Muscle injury in rhabdomyolysis may be direct (trauma), indirect (exertion, hyperthermia), or metabolic (ATP depletion leading to ion pump failure and intracellular calcium overload) (1, 5).

In pediatric populations, common triggers include: viral myositis (especially influenza B), the most frequent cause in children (5); exertional rhabdomyolysis, often seen in adolescent athletes (1); metabolic myopathies, including glycogen storage diseases, fatty acid oxidation defects, and mitochondrial disorders, which frequently present with recurrent episodes (2, 3); drugs, toxins, seizures, and electrolyte imbalances (1, 5, 6).

Why recurrent rhabdomyolysis merits attention

Acute kidney injury occurs in approximately 20-25% of pediatric rhabdomyolysis cases (6). When episodes are recurrent or severe despite minimal exertion, or when there is a family history of myopathy or malignant hyperthermia, metabolic or genetic causes should be investigated (3, 7).

Recurrent rhabdomyolysis can result from a wide range of inherited disorders, including defects in: fatty acid β-oxidation (*ACADVL*, *CPT2*, *HADHA*, *LPIN1*, *ACADM*), glycogen storage and glycolytic pathways (*PYGM*, *PGM1*, *PHKA1*, *AGL*), mitochondrial function, excitation-contraction coupling or ion channel regulation (*RYR1*, *SCN4A*), membrane-repair and structural myopathies (*DYSF*, *ANO5*, *FKRP*, *SGCA*, *SGCG*, *CAPN3*, *DMD*, *OBSCN*), and lipid and membrane homeostasis (*SMPD1*, *TANGO2*) (6-10).

Failure to recognize these underlying disorders may lead to repeated hospitalizations, preventable renal injury, and chronic kidney disease (6, 7). Conversely, early identification enables counseling, trigger avoidance, and potentially life-saving preventive strategies (5).

Diagnostic approach

A practical diagnostic approach for pe-

diatricians and nephrologists managing recurrent rhabdomyolysis should include the seven steps.

First step. *Initial Confirmation* using CK >5× the upper limit of normal or >1000 IU/L; Myoglobinuria (positive urine dipstick for blood without red cells) and the assessment of electrolytes, renal function, and urine output (1, 5).

Second step. *Evaluation of Triggers* involves review for infection, trauma, drugs, exertion, or fasting (2).

Third step. *"Red Flags"* warranting further work-up Two or more distinct episodes; No clear precipitating factor; Severe CK elevation or AKI; Early age of onset; Family history of myopathy; Persistent CK elevation between episodes (2,3).

Fourth step. *Identifying Genetic Susceptibility.* The RHABDO mnemonic helps distinguish patients whose rhabdomyolysis is disproportionate to external triggers (10) R (Recurrent episodes of exertional rhabdomyolysis), H (Hyperkalemia persisting >8 weeks after the event), A (Accustomed level of physical exercise), B (Blood CK >50× upper limit of normal), D (Drugs/medications/supplements or other factors insufficient to explain severity), O (Other family members affected or presence of exertional symptoms like cramps, myalgia).

Fifth step. *Second-Line Investigations* involves *metabolic screening* (free carnitine, acyl-carnitine profile, lactate/pyruvate, urine organic acids) and *targeted or panel-based genetic testing* (covering *ACADVL*, *ANO5*, *CPT2*, *DMD*, *DYSF*, *FKRP*, *HADHA*, *PGM1*, *LPIN1*, *PYGM*, *RYR1*, *AGL*, *CAPN3*, *CNBP*, *DMPK*, *MAGT1*, *ACADM*, *SCN4A*, *SGCA*, *SGCG*, *SMPD1*, *TANGO2*, *PHKA1*, *OBSCN*) (8-10).

Sixth step. *Management* by *a*ggressive intravenous hydration remains the cornerstone of therapy (1). Electrolyte imbalances and acidosis should be corrected, with early nephrology involvement in severe cases. Preventive measures include adequate hydration before exercise, avoidance of fasting, and education for families on early symptom recognition (3, 5).

Seventh step. *Follow-Up e*ven after recovery, CK and renal function should be monitored due to the risk of developing chronic kidney disease (7).

The Romanian context: gaps and opportunities

To date, no Romanian pediatric case series on recurrent rhabdomyolysis have been published. The limited national literature primarily focuses on adults or athletes (11). Romania continues to face challenges in metabolic screening. Newborn screening remains limited compared to other EU countries, and the nation retains the highest infant mortality rate in the Union (12). Although national infrastructure for rare diseases is improving, systematic data capture and registries are lacking (4).

These realities underscore the importance of developing a coordinated pediatric strategy, particularly in Iași, which hosts one of the country's leading medical universities and pediatric centers.

Recommendations for Romania

- Establish a national pediatric rhabdomyolysis registry, potentially under the Romanian Rare Disease Registry.
- Promote multidisciplinary collaboration among pediatric nephrology, neurology, and metabolic genetics specialists.
- Develop national guidelines for the evaluation of recurrent rhabdomyolysis, adapted from international best practices (5, 6).
- Expand access to metabolic and genetic testing across tertiary pediatric hospitals.

• Implement family education programs on early symptom recognition, hydration, and avoidance of known triggers.

In conclusion, recurrent rhabdomyolysis in children is a diagnostic "red flag" for underlying metabolic or genetic disease. Early recognition, comprehensive investigation, and preventive strategies can significantly reduce morbidity and mortality. Romania currently lacks pediatric data, registries, and structured diagnostic pathways. Establishing these resources will position national centers - particularly those in Iași - as leaders in pediatric metabolic medicine.

REMEMBERING ALZHEIMER'S LEGACY: 110 YEARS SINCE THE PASSING OF ALOIS ALZHEIMER

Motto: "A peculiar disease of the cerebral cortex has captured my attention, one that reveals itself through profound memory loss, confusion, and a progressive erosion of the mind."

Alzheimer's disease, a devastating neurodegenerative condition, was first brought to the world's attention in 1906 by the German psychiatrist and neuropathologist Alois Alzheimer (1).

His ground-breaking work began with the study of a 51-year-old patient, Auguste Deter, who exhibited unusual symptoms of progressive memory loss, confusion, and hallucinations-an alarming decline that could not be classified within the known medical conditions of the time (2). After her passing, Alzheimer meticulously examined her brain and discovered the presence of amyloid plaques and neurofibrillary tangles, marking the first recorded case of what would later bear his name (3).

While Alzheimer's contributions were pivotal, he did not work in isolation. His mentor, Emil Kraepelin, one of the most influential psychiatrists of his era, played a crucial role in formally recognizing the disease.

In the 1910 edition of his Textbook of Psychiatry, Kraepelin classified this newly identified disorder as a distinct form of dementia, differentiating it from other types of cognitive decline that typically appeared in old age (4).

At the same time, Czech psychiatrist Oskar Fischer was independently investigating dementia and arrived at remarkably similar conclusions. In 1907, Fischer conducted a meticulous postmortem analysis of 16 elderly patients suffering from cognitive decline. He documented the accumulation of abnormal protein formations in their brains-structures he named Sphaerotrichia cerebri multiplex, which closely resemble what we now call amyloid plaques (5).

Meanwhile, Romanian neurologist Gheorghe Marinescu made crucial discoveries that predated both Alzheimer and Fischer. Collaborating with French pathologist Paul Blocq in 1892, Marinescu was among the first to describe peculiar plaque-like formations in the brain's grey matter, which he termed "nodules of neuroglial sclerosis" (6).

Each of these brilliant minds played a vital role in shaping our understanding of Alzheimer's disease. Their collective efforts laid the foundation for modern neuropathology, offering early insights into the biological mechanisms that underpin dementia. Their discoveries, once confined to the pages of medical journals, have since fueled over a century of research, bringing us closer to unravelling one of the greatest medical mysteries of our time.

Our comprehensive analysis explores the evolution of Alzheimer's disease (AD) research, highlighting the key scientific breakthroughs that have shaped our understanding of its neuropathology, clinical presentation, imaging advancements, treatments, and future directions from the early 20th century to today.

EARLY 20TH CENTURY DISCOVERIES

• 1906 – Alois Alzheimer's Landmark Case: Alzheimer detailed the case of Auguste Deter, a 51-year-old woman with severe memory loss, confusion, and hallucinations. His post-mortem analysis revealed amyloid plaques and neurofibrillary tangles, establishing the foundation for AD pathology (1).

• 1910 – Emil Kraepelin defines AD: Kraepelin, a renowned psychiatrist and mentor to Alzheimer, formally named the disease in his Textbook of Psychiatry, distinguishing it from other dementias and cementing its place in medical literature (4).

• 1907 – Oskar Fischer's Parallel Discoveries: Fischer independently described amyloid plaques in dementia patients, analyzing 16 postmortem brains and identifying protein aggregates he termed "Sphaerotrichia cerebri multiplex." Despite the significance of his findings, they were overshadowed by Alzheimer's work (5).

• 1892 – Gheorghe Marinescu's Early Observations: Marinescu and Paul Blocq were among the first researchers to describe grey matter plaques, referring to them as "nodules of neuroglial sclerosis." Their work laid the groundwork for the later recognition of amyloid pathology in AD (7).

A B C D

Fig. 1. A – Alois Alzheimer, the German psychiatrist and neuropathologist who first identified Alzheimer's disease in 1906; B – Gheorghe Marinescu, the Romanian neurologist whose early work on senile plaques contributed to the understanding of neurodegeneration; C – Emil Kraepelin, the psychiatrist who formally classified Alzheimer's disease in 1910; D – Oskar Fischer, the Czech psychiatrist who independently described amyloid plaques in dementia patients in 1907.

The recognition and understanding of Alzheimer's disease emerged through the collective efforts of distinguished researchers, whose contributions, though shaped by different times and places, converged to define one of the most complex neurodegenerative disorders (fig. 1).

MID TO LATE 20TH CENTURY PROGRESS

• 1968 – Plaques Linked to Dementia: A quantitative neuropathological study confirmed that the density of senile plaques correlated with cognitive decline, solidifying the amyloid hypothesis (8).

• 1984 – Beta-Amyloid Identified: Scientists successfully isolated and characterized beta-amyloid as the primary component of AD plaques, marking a turning point in molecular research (10).

• 1986 – Tau Protein's Role Confirmed: Researchers discovered tau protein as a key

element of neurofibrillary tangles, reinforcing the dual-pathology model of amyloid and tau accumulation in AD (10).

• The pathological hallmarks of Alzheimer's disease (AD) include the accumulation of beta-amyloid plaques and neurofibrillary tangles, which contribute to neuronal dysfunction and degeneration. Beta-amyloid plaques form due to the abnormal aggregation of amyloid-beta peptides, disrupting synaptic communication and triggering neuroinflammation. Meanwhile, tau protein abnormalities lead to the formation of neurofibrillary tangles, destabilizing the microtubule network essential for intracellular transport. The progressive accumulation of these pathological structures results in widespread neuronal loss, cortical atrophy, and cognitive decline, characteristic of AD (fig. 2).

NIH; 2024); B – Neuronal degeneration in Alzheimer's disease, showing the widespread cellular damage caused by beta-amyloid accumulation and tau pathology (Source: Getty Images. Neuronal Degeneration in Alzheimer's Disease. Getty Images, 2024).

21ST CENTURY ADVANCEMENTS

• 2000s – Imaging Revolution: Advanced MRI and PET (fig. 3) scans transformed the ability to visualize AD-related brain changes, confirming that atrophy often begins in the medial temporal lobes, particularly in the hippocampus, before spreading to parietal and frontal regions (11).

• 2024 – Breakthrough in Blood-Based Diagnostics: A new blood test demonstrated 90% accuracy in detecting AD pathology, paving the way for early diagnosis and intervention (12).

Regional Brain Atrophy in AD

Research has mapped the progression of atrophy in AD, revealing a distinct pattern of neurodegeneration:

• Temporal Lobes: Early and severe atrophy (up to 30%) impairs sensory processing, language comprehension, and memory formation (13).

• Hippocampus: As a key structure for memory consolidation, its progressive shrinking correlates with the severity of cognitive decline (14).

• Frontal Lobes: As the disease advances, the executive function centers responsible for decision-making, planning, and social behavior deteriorate (15).

• Parietal Lobes: Spatial orientation and navigation abilities decline, contributing to disorientation, apraxia, and visuospatial deficits (16).

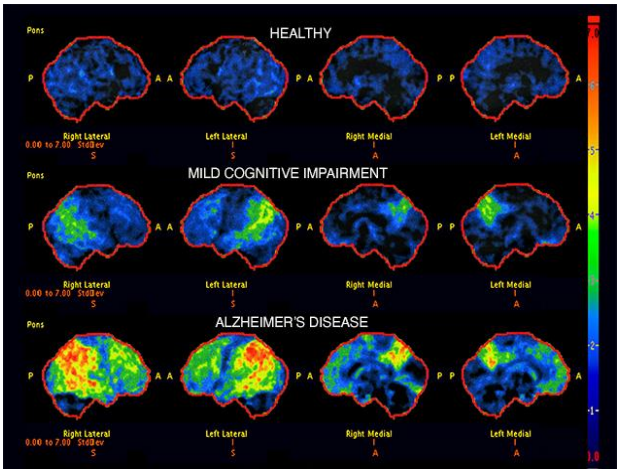

Fig. 3. PET scans illustrating progressive glucose hypometabolism from a healthy brain (top) to mild cognitive impairment (middle) and Alzheimer's disease (bottom), highlighting neurodegeneration in key brain regions (Source: Mayo Clinic. Brain scan images for diagnosis of Alzheimer's disease. Available at: https: //www.mayoclinic.org/diseases-conditions/alzheimers-disease/multimedia/img-20543518)

TREATMENT DEVELOPMENTS

Over the years, Alzheimer's disease treatments have evolved from symptomatic management with cholinesterase inhibitors in the 1990s to disease-modifying therapies targeting amyloid pathology, such as Aducanumab (2021) and Lecanemab (2023). These advancements reflect a shift toward addressing the underlying neurodegenerative mechanisms rather than just symptom relief (tab. I).

TABLE I.

Major Treatment Milestones in Alzheimer's Disease

Year	Treatment	Mechanism	Impact
1990s	Cholinesterase Inhibitors (Donepezil, Rivastigmine)	Enhances acetylcholine levels to improve cognition	Modest symptom relief in mild to moderate AD (17)
2003	Memantine	Regulates glutamate activity to prevent excitotoxicity	Approved for moderate to severe AD (18)
2021	Aducanumab	First disease-modifying therapy targeting amyloid plaques	Controversial, but approved under accelerated pathway (19, 21)
2023	Lecanemab	Anti-amyloid therapy with confirmed efficacy in slowing cognitive decline	First fully FDA-approved disease-modifying therapy (20, 21)

FUTURE PERSPECTIVES

The next frontier in AD research focuses on early detection, precision medicine, and novel therapeutic targets:

- Targeting Tau Aggregation: Therapies are being developed to prevent or reverse tau pathology, a key driver of neurodegeneration (22).
- Neuroinflammation Modulation: Investigations into microglial activation and inflammatory pathways may lead to immunotherapies that slow disease progression (23).
- Synaptic Protection Strategies: Scientists are exploring ways to enhance neuro-

plasticity and synaptic resilience, aiming to preserve cognitive function despite disease pathology (24).

In conclusion, the evolution of Alzheimer's disease (AD) research is a testament to the contributions of pioneering scientists who shaped our understanding of this devastating neurodegenerative disorder. From Alois Alzheimer's meticulous observations in 1906, which first linked cognitive decline to amyloid plaques and neurofibrillary tangles, to Emil Kraepelin's formal classification of the disease in 1910, their foundational work paved the way for modern neurology and psychiatry.

At the same time, Oskar Fischer independently described amyloid pathology in dementia patients, yet his findings were largely overshadowed by historical circumstances. Similarly, Gheorghe Marinescu's early recognition of neuroglial nodules in the brain was a key, yet underappreciated, milestone in AD research. These early scientists, each working in different parts of Europe, laid the groundwork for the neuropathological discoveries that still define AD today.

Over the past century, technological advancements have dramatically expanded our ability to study and diagnose AD. Imaging techniques like MRI and PET scans now allow for early detection, while biomarker research in cerebrospinal fluid (CSF) and blood has revolutionized diagnostic accuracy. What once required a post-mortem brain analysis can now be identified decades before symptoms appear, offering hope for earlier intervention.

Therapeutic advancements have also reflected a shift from symptomatic treatment to disease modification. The introduction of cholinesterase inhibitors in the 1990s, followed by memantine in 2003, provided temporary relief but failed to halt disease progression. More recently, Aducanumab (2021) and Lecanemab (2023) have opened a new chapter in AD treatment, focusing on amyloid clearance, though their long-term efficacy remains debated.

Despite a century of research, AD remains an incurable condition, with millions worldwide facing its relentless progression. The future of AD research lies in targeting not just amyloid and tau pathology, but also neuroinflammation, synaptic dysfunction, and genetic risk factors. As we move forward, the contributions of early pioneers like Alzheimer, Kraepelin, Fischer, and Marinescu serve as a reminder that scientific discovery is built on the perseverance of those who dare to question, observe, and innovate.

EDITORIAL

NEUROGASTROENTEROLOGY - A NEW FIELD?

Over the past decades, Gastroenterology has undergone a profound transformation, moving beyond a purely organ-centered approach toward an integrated, multidisciplinary understanding of digestive diseases. At the heart of this evolution lies Neurogastroenterology, a field dedicated to the complex interactions between the gastrointestinal tract, the enteric nervous system, and the central nervous system. Neurogastroenterology has emerged as a distinct and essential subspecialty, dedicated to the study and management of disorders arising from dysfunctions of the gut-brain axis. In this context, the establishment and development of a Neurogastroenterology unit represents not only a scientific advancement, but also a clinical necessity for contemporary medicine.

Neurogastroenterology addresses a wide spectrum of conditions that are highly prevalent, clinically challenging, and often associated with significant patient suffering. In general population, disorders such as irritable bowel syndrome (4.1%), functional dyspepsia (7%), functional esophageal disorders (functional heartburn ~ 2-3%, globus sensation ~ 3-4%, functional chest pain ~ 1-2%), functional constipation (~11-14%), and fecal incontinence (1.5-2.5%) are now collectively classified as disorders of gut-brain interaction (1). These conditions affect millions of individuals worldwide, impose a considerable socioeconomic burden, and frequently lead to repeated medical consultations, extensive investigations, and therapeutic frustration for both patients and clinicians. Despite their prevalence, such disorders have long been marginalized, often perceived as diagnoses of exclusion or as conditions lacking a solid biological basis. The development of a dedicated Neurogastroenterology unit plays a crucial role in overcoming these misconceptions and in providing structured, evidence-based care.

A defining feature of Neurogastroenterology is its focus on the complex pathophysiological mechanisms underlying gastrointestinal symptoms. Research over recent decades has demonstrated that altered gastrointestinal motility, visceral hypersensitivity, dysregulation of central pain processing, autonomic nervous system imbalance, immune activation, and changes in the intestinal microbiota all contribute to symptom generation. These biological factors interact dynamically with psychological and social determinants, including stress, anxiety, depression, early life adversity, and coping mechanisms. A Neurogastroenterology unit provides an integrated framework in which these multifactorial mechanisms can be systematically evaluated and therapeutically targeted (1).

From a diagnostic standpoint, the Neurogastroenterology unit offers access to specialized functional investigations that are essential for accurate diagnosis and patient stratification. High-resolution esophageal and anorectal manometry, impedance-pH monitoring, gastric emptying studies, colonic transit assessments, breath tests for carbohydrate malabsorption and small intestinal bacterial overgrowth, as well as tests of anorectal sensory and motor

function, enable clinicians to move beyond symptom-based criteria toward mechanism-oriented diagnoses (2). This approach facilitates more precise phenotyping of patients, allowing clinicians to distinguish between motility disorders, sensory abnormalities, and central dysregulation. Such diagnostic precision is fundamental to the principles of personalized medicine and is associated with improved therapeutic outcomes (3).

Equally important is the therapeutic philosophy promoted within a Neurogastroenterology unit. Management strategies are inherently multimodal and individualized, reflecting the heterogeneity of underlying mechanisms.

Pharmacological treatments may include agents that modulate gastrointestinal motility, secretion, and visceral sensitivity, as well as centrally acting neuromodulators targeting pain processing and affective components of symptoms. Dietary interventions, such as low fermentable oligo-, di-, monosaccharides and polyols (FODMAP) diets or targeted nutritional modifications, play an increasingly important role. Psychological therapies, including cognitive behavioral therapy, gut-directed hypnotherapy, and stress management techniques, have demonstrated efficacy in selected patient populations. The coordinated integration of these approaches within a dedicated clinic fosters a holistic and patient-centered model of care (4).

Interdisciplinary collaboration represents another cornerstone of the Neurogastroenterology unit. Close cooperation between gastroenterologists, neurologists, psychiatrists, psychologists, dietitians, physiotherapists, and specialized nurses enhances both diagnostic accuracy and therapeutic effectiveness. Such collaboration is particularly valuable in patients with severe, refractory, or chronic symptoms, who often present with overlapping gastrointestinal and extraintestinal complaints. By addressing both somatic and psychosocial dimensions of disease, the Neurogastroenterology department contributes to improved quality of life, reduced symptom burden, and greater patient satisfaction.

Beyond its clinical impact, the Neurogastroenterology unit fulfils a vital role in medical education. Functional gastrointestinal disorders are frequently underrepresented in undergraduate and postgraduate curricula, despite their high prevalence in everyday practice. Exposure to a structured Neurogastroenterology service allows medical students and residents to develop a nuanced understanding of gut-brain interactions, diagnostic reasoning in functional disorders, and the principles of biopsychosocial medicine. This educational experience helps counteract therapeutic nihilism and fosters empathy toward patients whose symptoms may be invisible yet profoundly disabling (4). For practicing clinicians, Neurogastroenterology clinics serve as centers of excellence that promote continuing professional development and dissemination of updated clinical guidelines.

The academic value of a Neurogastroenterology clinic is further reflected in its contribution to clinical and translational research. The gut-brain axis represents one of the most dynamic areas of contemporary biomedical research, with ongoing investigations into neuroimmune signaling, microbiota-brain communication, and novel therapeutic targets. Dedicated clinics provide well-characterized patient populations, standardized diagnostic protocols, and opportunities for longitudinal follow-up, all of which are essential for high-quality research. Participation in multicenter studies and international collaborations enhances scientific visibility and positions academic institutions at the forefront of innovation in digestive health.

Within the context of academic medicine in Iași, a city with a long-standing tradition of medical scholarship and clinical excellence, the development of a Neurogastroenterology clinic carries particular significance. It aligns with the mission of tertiary care centers to address complex and unmet clinical needs while integrating education and research. Moreover, it responds to the growing demand for specialized care among patients with functional gastrointestinal disorders, who often experience delays in diagnosis and fragmented care pathways. Establishing a dedicated clinic not only improves access to expertise but also reinforces the role of the academic hospital as a reference center for the region. Academician Professor Doctor Carol Stanciu had a pivotal role in introducing functional gastrointestinal investigations in Iasi. Through his vision and dedication, modern diagnostics techniques such as motility and functional testing were improving both clinical practice and academic training (5).

In conclusion, the importance of a Neurogastroenterology unit in contemporary medical practice cannot be overstated. By providing specialized diagnostic tools, individualized and multimodal therapies, interdisciplinary collaboration, and opportunities for education and research, such clinics address a major gap in the care of patients with disorders of gut-brain interaction. Their role extends beyond symptom management, contributing to a deeper understanding of disease mechanisms and to the advancement of integrative medicine.

In academic centers such as Iași, the consolidation of Neurogastroenterology services represents both a continuation of medical tradition and a forward-looking investment in the future of patient-centered care.

EDITORIAL

ART AND SCIENCE IN CARDIOVASCULAR DISEASE

As the progress in technology and pharmaceutical domain resulted in effective solutions for transmissible diseases such as cholera or poliomyelitis which caused millions of deaths worldwide in the past, the importance of cardiovascular disease was brought into the spotlight. Many lifesaving interventions such the percutaneous angioplasties in acute myocardial infarction led to an important impact in the survival rates increasing longevity. Furthermore, the prevention of cardiovascular disease has proven to be both effective and cost-efficient. The 2016 "European Guidelines on Cardiovascular Disease Prevention in Clinical Practice" clearly states that stopping smoking is the most cost-effective strategy for cardiovascular disease prevention (1).

Smoking is pandemic, with a worldwide prevalence of 1 billion smokers in 2011 (2). Although the rate of smoking is declining in Europe, it remains very common and is increasing in women, adolescents and the socially disadvantaged (3). A recent study performed in 187 countries to estimate the prevalence of daily smoking by age and sex and the number of cigarettes per smoker per day from 1980 to 2012 showed that the prevalence of daily tobacco smoking decreased from 41.2% in 1980 to 31.1% in 2012 for men and from 10.6% to 6.2% for women (4). The prevalence declined at a faster rate from 1996 to 2006 compared with the subsequent period, but despite the decline in prevalence, the number of daily smokers increased from 721 million in 1980 to 967 million in 2012 in the context of population growth (4).

From the economical point of view, data are also alarming. In a studied performed in 152 countries, representing 97% of world's smokers, researchers found that diseases caused by smoking accounted for 5.7% of global health expenditures in 2012, while the total economic cost of smoking was equivalent to 1.8% of global gross domestic product (5). Furthermore, smoking caused 2.1 million deaths and 13.6 million years lost to disability among adults aged 30-69 (5). In total, smoking-attributable diseases accounted for 12% of all deaths among the world's working-age population, with this proportion being highest in Europe and America where the tobacco epidemic is most advanced (5).

The statistics outlining the negative effect of tobacco consumption are plenty. A lifetime smoker has a 50% probability of dying due to smoking, and on average will lose 10 years of life (6). Smoking is responsible for 50% of all avoidable deaths in smokers, half of these due to cardiovascular disease (1), as smoking accounts for 36% of the risk attributable to a first myocardial infarction (7).

Is there any reasonable explanation for this pandemic of an apparently evidence-based proven lethal behavior? Maybe there is.

Looking back in history we see that the perception of smoking suffered important changes along the years reflecting the changing mentalities of the society, influenced by both discoveries in the medical field, political and industrial interests.

After its introduction to Europe by Christopher Columbus in1492, tobacco conquered the world. It was believed to have miraculous powers as suggested by Robert Burton in his "The Anatomy of Melancholy" (1621): "Tobacco, divine, rare, superexcellent tobacco, which goes far beyond all panaceas, potable gold and philosopher's stone, a sovereign remedy to all diseases" (8). Books like "Panacea or the Universal Medicine, being Discovery of the Wonderful virtues of tobacco taken in Pipe with its Operation and use both in Physick and Chyrurgery" (1624) or "Tabacologia" describe various positive effects of tobacco. It was the "holy herb" of the mid-sixteenth century and the penicillin of the seventeenth century (8). The first to oppose the use of tobacco was King James I of England who declared it to be immoral and unhealthy in his "Counterblaste to Tobacco" from1604 while in 1956 Auerbach documented the cardiopulmonary disorders and malignancies that resulted from the use of tobacco (8).

As the perception of smoking changed in society along the history so did the connotation attached to the artistic representation of smoking in art. Following the artistic representation of smoking we can indirectly track the evolution of society`s perception toward a major cardiovascular risk factor.

In his chapter "Symbol and Images: Smoking in Art since the Seventeenth Century" from the "Smoke. A Global History of Smoking", Benno Tempel provides a brilliant illustration of the multiples changes in meaning associated with the artistic representation of smoking (9). In the seventeenth century the representation of smoking in art was associated with lower class society, drunkenness and social deviance (10) as depicted by Dutch painters such as Gerard ter Borch and the Flemish artist David Teniers the Younger. In the eighteenth century, it depicted eroticism and pleasure as in the artworks by Antonia Guardi, Joseph Vernet and Jean Etienne Liotard depicting harem women smoking to emphasize their erotic passivity and boredom (9). In the nineteenth century, smoking pointed out social differences as it was exclusively the privilege of men (9). During the Romantic period smoking became tightly related to intellectualism, literature and creation as illustrated by the Edouard Manet's "Stephane Mallarme". The Impressionists painted smoking scenes as a part of the everyday life, with no additional meanings. Smoking regained the symbolic power in the postimpressionist era when artists like Edvard Munch used smoking to symbolize psychological problems as in his "Self-Portrait". In the 20th century smoking in art exhibited a wide variety of connotations ranging from social and economic status to the decrease of smoking attractiveness which was captured by artists like Mel Ramos and Tom Wesselmann who exploited the clichés of sex and cigarettes (9).

The representation of smoking in art had a great influence on the smoking phenomena in women. While initially smoking was inacceptable for women, the illustration of female smoking denoting prostitutes as painted by Henri Toulouse-Lautrec and Vincent van Gogh, after 1900 it gradually became a symbol of charm, the representation of women smoking in art making it a more social acceptable habit (9).

Wilson and colleagues (11) exemplified the important symbolic power of the representation of smoking in art along the years in their work "Might artworks from online-

museum collections contribute to medical education?" In January 2014, they identified artworks with tobacco smoking content by analyzing the Google Cultural Institute's "Art Project" which comprised 309 art collections from 49 countries, namely 55,004 artworks by 8654 named artists (11). There were 356 artworks with smoking content spread over five centuries: 1600s (5.9%), 1700s (6.7%), 1800s (43.3%), 1900s (37.1%), and 2000s (7.0%). Paintings (at 66.0%), predominated over other forms such as photographs (18.8%) and drawings (10.7%) (11). They illustrated the different meanings of tobacco smoking by selecting 10 representative artworks. Smoking in art was attached to a wide variety of meanings ranging from immoral behaviors, drunkenness, sexual licentiousness, reflected the epidemic of female smoking, its association with alcohol, sensuality, sexuality, nonconformity, rebelliousness, mental disorders or glamour (11).

Another very interesting study performed by Wilson and colleagues (12) analyzed the artworks produced between 1950-1999 and exhibited in The National Portrait Gallery in London finding 53 portrayed smoking by identifiable individuals (5%) out of the 1063 artworks of the collection. They found that the rate of portrayal was highest in the 1950s (10%) and 1960s (11%) and declined sharply thereafter, smoking virtually disappearing from portraiture in the 1990s (12). As expected, men were more often represented than women with predominant occupations of writers, painters, artists, and politicians while there were no portrayals of smoking among scientists, engineers, mathematicians, astronomers, inventors, and doctors (12). Cigarettes were the dominant form of tobacco product (64% of portrayals), followed by pipes (26%), and cigars (9%) (12).

Apart from the awareness induced by the evidence based medical effects of tobacco, the industry of media and entertainment had a great importance in the history of smoking, as tobacco use in movies and television is a subtle and powerful form of promotion (13).

The article "How the tobacco industry built its relationship with Hollywood" (13) brings into the spotlight secret internal tobacco industry documents. The declarations of important figures of the tobacco industry and correspondence with the movie industry help us understand the continuous siege we are intentionally exposed to increase the tobacco consumption.

As early as 1792, the tobacco industry realized that product placement in movies is "better than any commercial that has been run on television or any magazine, because the audience is totally unaware of any sponsor involvement" (13, 14). The tremendous power of smoking on screen is brilliantly exposed in a Philip Morris marketing plan from 1989: "We believe that most of the strong, positive images for cigarettes and smoking are created by cinema and television. We have seen the heroes smoking in "Wall Street", "Crocodile Dundee", and "Roger Rabbit". Mickey Rourke, Mel Gibson and Goldie Hawn are forever seen, both on and off the screen, with a lighted cigarette. It is reasonable to assume that films and personalities have more influence on consumers than a static poster of the letters from a B&H pack hung on a washing line under a dark and stormy sky. If branded cigarette advertising is to take full advantage of these images, it should do more than simply achieve package recognition-it has to feed off and ex-

ploit the image source" (13, 15). Moreover, documents from 1980 reveal that the tobacco industry required specific criteria for tobacco product placement in a film like "positive exposure", that the stars are people "with whom we would want the product associated", and if "we could work the product into the script" (13,16).

The article (13) explains in detail and exemplifies with concrete situations how tobacco industry understood the value of placing and encouraging tobacco use in films. The strategies included placing products and tobacco signage in positive situations on screen, while keeping brands away from negative situations, writing favorable articles related to smoking, encouraging professional photographers to take pictures of actors smoking specific brands, paying and even offering free cigarettes to producers and famous celebrities to use a certain brand in real life and on the screen. It also specifies movies where smoking-related products were used - "Superman II", "The Jazz Singer", "Backroads", "Cannonball Run", "Pennies from Heaven", "Blowout", "Falcon's Crest", "Dallas", "Knot's Landing", "Grease", "Rocky II", "Airplane", "Little Shop of Horrors", "Crocodile Dundee", "Die Hard", "Who Framed Roger Rabbit", and "Field of Dreams (13, 17).

The intense activity of the tobacco industry reflected in the prevalence of smoking scenes in the movies. A random sample of top-grossing films from 1950 through 2002 indicated that the amount of smoking decreased from an average of 10.7 events per hour in 1950 to a low of 4.9 events per hour in 1980-1982 and then increased rapidly to 10.9 events per hour in 2002 (18).

Researchers pointed out that movies rarely depict the negative health outcomes related to smoking and contribute to increased perceptions of smoking prevalence and association with benefit such as glamour, independence, rebelliousness, relaxation, stress relief, romance, socializing, celebrating, pensive thinking, and confiding in others (18).

In an analysis of how smokers were depicted in 100 popular films from 1940 to 1989 McIntosh and colleagues found that smokers were depicted as more romantically, more sexually active and more intelligent than nonsmokers showing that Hollywood's depiction of smoking tends to ignore the negative consequences while depicting smokers a bit more positively than nonsmokers (19).

Under these circumstances of movies depicting an increased prevalence and benefits of smoking, the impact of movie industry upon youth became extensively studied.

In 2002 Sargent and colleagues provided empirical evidence that viewing movie depictions of tobacco use is associated with higher receptivity to smoking prior to trying the behavior (20).

Charlesworth and colleagues concluded in 2005 that smoking in the movies leads adolescents to hold more protobacco attitudes and beliefs, which is consistent with the observed dose-response relationship between exposure to smoking in the movies and initiation of adolescent smoking (18). The images of smoking in movies both normalize the behavior and downplay the negative health effects associated with smoking, encouraging more tolerant, neutral, or nonchalant attitudes about smoking, establishing the perception that smoking is normal, prevalent, and even desirable in society, especially among adults (18). Although teens generally acknowledge the long-term health risks associated with

smoking, they immediately experience the perceived short-term benefits of smoking, such as looking tough or sexy or fitting in with their peers, which reinforces and motivates adolescent smoking (18).

It is argued that according to a population-attributable risk calculation movies account for almost 390 000 new adolescent regular smokers in the United States annually (21) which is nearly equal to the 400 000 (22) active smokers that die every year.

In 2016, the first meta-analysis of longitudinal studies of the association between exposure to smoking imagery in movies among young people and the risk of becoming a smoker show that the most exposed young people are more than 40% more likely to become smokers than the least exposed (23).

There is a tight connection between art and science in the society's perception of smoking. The artistic representation of smoking is associated with a wide variety of connotations along the centuries ranging from poverty, decadence, elegance, intellectuality, romance, to destruction and death. The movie on the other hand, mainly due to the tobacco industry interests, tends to associate smoking with favorable stereotypes while omitting it's the negative effects with deleterious impact on the youth.

ROLE OF THE REHABILITATION HOSPITAL IN THE SOCIAL AND ECONOMIC INTEGRATION OF PERSONS WITH DISABILITIES

Roxana Maria Cauneac[1], G. Stefan[2], Mihaela Carausu[3], I.S. Stratulat[4*]

ROLE OF THE REHABILITATION HOSPITAL IN THE SOCIAL AND ECONOMIC INTEGRATION OF PERSONS WITH DISABILITIES (Abstract): **Aim**: The perceptions towards disability and the disability legislation has changed over the last years. However, for the persons with disabilities and their families a clear path to follow to manage their conditions and successfully integrate in the economic and social life has not been established, yet. **Material and methods**: Analysis of the status of disability practice in Europe and in our country, and an attempt to establish the role of the rehabilitation doctor and regional rehabilitation hospital in the long-time management of these patients. **Results**: The largest share of a hospital income is based on contracts with the National Health Insurance Agency, so all rehabilitation procedures conducted during hospitalization must fit into standardized protocols developed by expert committees. The same is true for the outpatient rehabilitation. **Conclusions**: Many aspects would require improvement in our country and it is the duty of the rehabilitation doctor to ensure personalized care for all patients. Therefore, there is a need for some changes, starting with attracting collateral funding, implementation of national healthcare programs and establishment of non-governmental agencies. **Keywords:** DISABILITY, REHABILITATION HOSPITAL, SOCIAL REINTEGRATION.

Disability is a generic theme, a so-called "problem" recognized worldwide. However, it is socially problematic to define clearly and to establish concrete terminology in this relatively controversial area.

Regarding the antithesis disability-ability, we subjectively establish a degree of normality of the population, to establish later, subjectively, the disability (1).

Disability should not be seen and should not be an impediment to success - neither for the patient nor his/her family, nor for the "auxiliary" people involved in this issue.

Reactions to disability have changed over time, largely because people with disabilities started to unite in associations and non-governmental organizations (NGOs), which has led to various national and international initiatives to support them (2, 3, 4, 5).

Adopting and organizing a quality man-

agement system centered on personalized healthcare should be a strategic decision of each hospital. The design and implementation of such a system is primarily the duty of the manager, being influenced in this respect by specific needs and objectives, the services he provides and which he intends to implement in the future, and by the size, structure and profile of the unit he is leading (6).

Patients with disabilities must be effectively integrated socio-economically to contribute within the limits allowed by the type and degree of disability to the country economic growth. Thus, disability costs will be more easily borne by both patients and family, and by the society (7, 8, 9).

Because a great part of the rehabilitation and integration of people with disabilities is realized in the community it is our duty as doctors to ensure the continuity of this rehabilitation by establishing good collaborative relationships with the state institutions and various NGOs that manage these patients, to facilitate their access to continuous rehabilitation services, avoiding bureaucratic obstacles (8, 9).

MATERIAL AND METHODS

We evaluated the role of a rehabilitation hospital, the Botosani "Sf. Gheorghe" Rehabilitation Hospital, in the social and economic integration of persons with disabilities.

Several management, quality-of-care and financial indicators, the implementation of social policies in the Botosani Rehabilitation Hospital and Botosani county, as well as the status of management of the people with disabilities nationwide were assessed.

The statistical analysis was performed using *SPSS 18.0* software (SPSS Inc., Chicago, IL, USA).

We also wrote a series of proposals and plans management of these people, to fulfil objective needs and increase their active participation in the social and economic life.

Medical services are provided by two clinics of Rehabilitation, Physical Medicine and Balneology (RMFB) with separate compartments for neurological, cardiovascular and pulmonary rehabilitation, a department of rheumatology, and one of geriatrics-gerontology, totaling 195 beds. The clinic also has a 25-bed short-stay unit and 7 outpatient consulting rooms: internal medicine, ENT, rheumatology, neurology, rehabilitation, physical medicine and balneology, geriatrics and gerontology, ophthalmology. Medical rehabilitation services are provided in the treatment base (10).

The hospital also has a medical laboratory, a functional exploration laboratory and a medical radiology and imaging laboratory.

Within the hospital, until 2014, the National Program for Active Monitoring of People with Disabilities was functioning.

Botoşani County is in North-east part of Romania, with a total area of 4,986 km^2. The administrative-territorial organization of Botosani County in municipalities, towns, communes and villages has the following proportions: 2 municipalities, 5 towns, 71 communes and 333 villages. Botosani municipality, located in northeastern Romania, is the largest town and the capital of Botosani County; it has a population of about 115,000 inhabitants (11).

The total population of the county is 397,151 inhabitants (2015), distributed as follows (12): 196,905 (49.6%) male inhabitants and 200,246 (50.4%) female inhabitants; 161,518 (40.7%) urban population

and 235,633 (59.3%) rural population.

Age-group distribution: children and students (0-19 years): 98,324; active age population (20-64 years): 226,648; elderly (≥ 65 years): 72,179 inhabitants (11).

The distribution of the hospital staff is as follows (11): total jobs approved on 31 December 2016: 206, of which: 3 for the Steering Committee, 22 doctors, 8 health professionals with higher education, 92 nurses, 51 auxiliary staff, 12 technical, economic and socio-administrative staff and 18 workers (11).

The distribution of hospital beds over the different units is as follows (6): Department of Rehabilitation, Physical Medicine and Balneology I- 90 beds, of which 34 beds for Neurological Rehabilitation Department, 56 beds for the Department of Rehabilitation, Physical Medicine and Balneology, 15 beds for Rheumatology Department and 24 beds for Geriatrics and Gerontology Department. The Department of Rehabilitation, Physical Medicine and Balneology II has 66 beds, of which 26 beds for Cardiovascular rehabilitation, 12 beds for pulmonary rehabilitation, 22 beds for Rehabilitation, Physical Medicine and Balneology and 25 beds for the short-stay unit (6).

RESULTS

The number of patients discharged in 2016 was 4961 (fig. 1), of which 2,442 (49,2%) from the Department of Rehabilitation, Physical Medicine and Balneology I, 1711 (34,48%) from the Department of Rehabilitation, Physical Medicine and Balneology II, 313 (6,3%) from the Rheumatology Department and 495 (9,97%) from the Geriatrics and Gerontology Department (11).

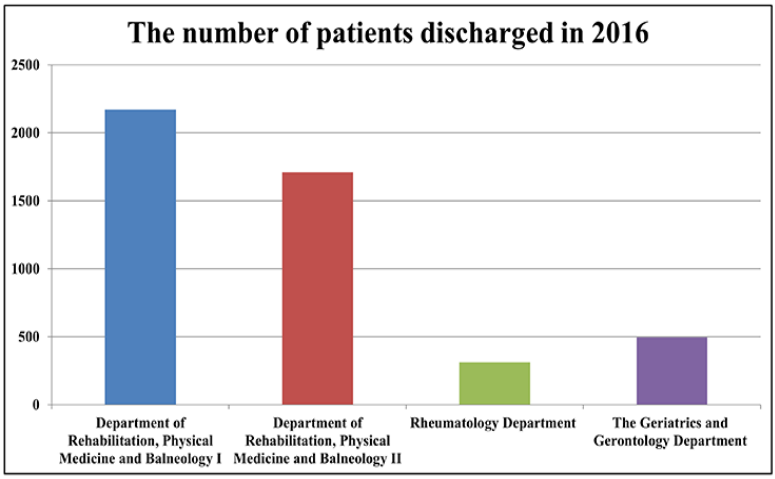

Fig. 1. The number of patients discharged in 2016

Assessment of the economic and financial situation of the hospital

From table I, the highest share of the hospital income is represented by contracts with the National Health Insurance House (CNAS) (more than 90% over the whole analysis period). At the same time, it is noticed that the percentage of income from other sources, i.e. hospital own incomes, is decreasing (from 5.62% in 2014 to 4.26%

in 2016).

Analyzing the expenditures over the period 2014-2016 (tab. II), it is noticed that the largest share of the total expenditures is for personnel expenditures. At the same time, the percentage of these expenditures is increasing, which is explained by the fact that, starting with 2015, the salaries of employees increased because of Ordinances no 35/2015, 20/2016, 43/2016 and Law no 250/2016.

TABLE I

Income structure by funding sources (years 2014-2016) (RON) (12)

	Funding source	2014	2015	2016
A	**CNAS contracts**	**8,835,418 (92.4%)**	**8,991,405 (92.55%)**	**11,241,973 (91.06%)**
1.	Continuous hospitalization	8,195,449	8,034,848	10,142,753
2.	Short stay unit	161,155	256,212	273,793
3.	Laboratory	152,774	303,618	385,572

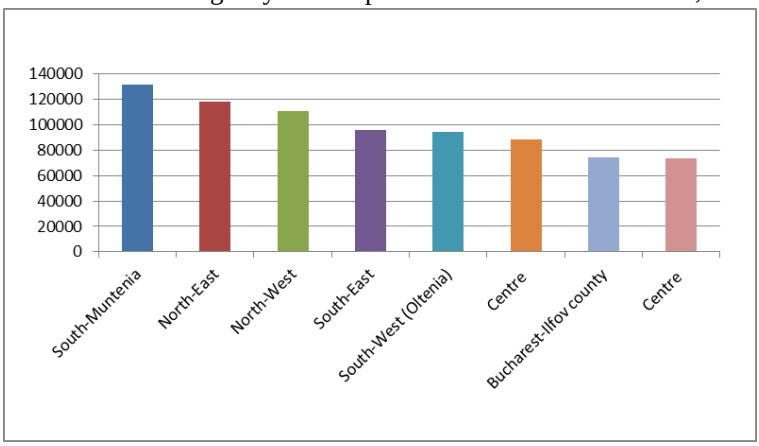
The implementation of social policies for people with disabilities

According to the World Health Organization Report (2), the prevalence of people with disabilities varies with age and disability; there is a slightly higher percentage of people with both severe and moderate disabilities in Europe compared with the rest of the world.

On December 31, 2016, the total number of adults with disabilities in Romania was of 786,546, of which 768,456 (97.7%) in the care of families (not institutionalized) and 18,090 (2.3%) institutionalized (12).

TABLE III
Total number of persons with disability in Romania
(Source: National Agency for People with Disabilities – ANPD, 2016)



Regarding the regional distribution, according to the National Agency for People with Disabilities (ANPD), the number of people with disabilities in the Northeast Romania is 118,304 (tab. III). According to ANPD, this region is ranked second at national level in terms of the number of people with disabilities (12).

The national distribution places Botosani County under the average of 18727.28 (total number of disabled persons/total number of counties), with an effective number of persons with disabilities of 13577. Most adults have a physical disability, followed by people with a somatic and mental disability (11).

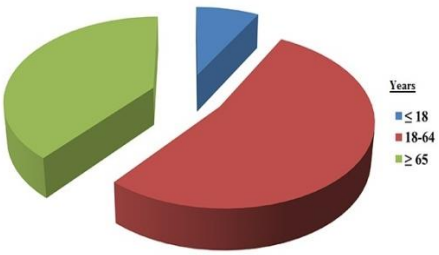


Fig. 2. Age-group distribution of people with disabilities

Age-group distribution reveals that the highest percentage of people with disabilities is in working age age-group (18-64 years) - 53%, followed by the age group over 65 years- 39% (11) (fig. 2).

DISCUSSION

Through this paper it is desirable to promote patient-centered and disability-based healthcare using the medical-social support hexadecimal scheme, and to promote personalized healthcare.

It is also important to seek and attract short, medium and long-term funding sources to be able to provide long-term rehabilitation health care and to make partnerships with governmental institutions and non-governmental organizations.

An important part in these actions is promoting them in the media by organizing interdisciplinary events at the hospital level with the involvement of social workers in partnerships: doctors, nurses, social workers, occupational therapists, psychologists, priests, organizing and coordinating support groups for patients with disabilities, in partnership with social assistance services at the

level of local authorities, organizing and coordinating programs and projects at local level for the socio-economic and professional reintegration of people with disabilities.

Designing and printing informative materials (flyers, brochures) and promoting existing ones (sites, leaflets, brochures) for patients, family, can be useful to properly orientate to social assistance services.

The rehabilitation physician's duty is to increase the quality of life of patients with a certain degree of disability; hence the obligation to identify patients at risk (elderly, disadvantaged, vulnerable or non-functional).

Development of programs for the continuous rehabilitation of people with disabilities by organizing thematic meetings with the participation of patients, the family, as well as the medical staff involved in rehabilitation: specialized doctors, nurses, social workers, occupational therapists, psychologists and collaborations and partnerships with companies that sell or distribute healthcare devices at home; good cooperation with the National Health Insurance Agency and the county branches can be also useful in order to provide financial assistance to the patient for the purchase and use of these types of devices.

Another useful action would be to establish a loco-regional database of patients with disabilities to properly track their everyday work for socio-economic-professional integration.

In the end, an important step would be the establishment of a non-governmental association / non-profit foundation to acquire an infrastructure of medical devices and home care facilities available on loan for patients with a certain degree of temporary disability (e.g., chairs or cradles, crutches, walking sticks, prostheses, prostheses or non-personalized orthotics, special mattresses, mobilization or transfer devices etc.).

CONCLUSIONS

This study shows that establishing protocols for admission and treatment during hospitalization is strictly necessary in the Botosani Rehabilitation Hospital.

Community social rehabilitation and social reintegration assistance must start in the hospital.

During the hospitalization, it is necessary to have a complex interdisciplinary team (psychologist, occupational therapist, social worker etc.).

Post-acute cases with moderate and low disability levels will be analyzed through diagnostic protocols and rehabilitation therapy to be able to follow the outpatient treatment.

Social cases will be discharged after analysis with the region's NGOs.

Home treatment will be reviewed together with local specialist companies that can ensure proper care for the patient.

The readmission of aggravated chronic cases requiring hospital admission will be assessed based on specific protocols for each pathology.

NEWS

ROLE OF AML SPECIFIC CYTOTOXIC ANTIBODIES IN GVL RESPONSE

It is well established that most acute myeloid leukemia (AML) patients can obtain remission only by means of allogenic hematopoietic stem cell transplant(HSCT). This process induces a graft versus leukemia immune response (GvL) mediated by T cells and NK cells. However, there is not much data showcasing the contribution of B lymphocytes, so a study was conducted that focused on B cells producing monoclonal antibodies against antigens expressed on the cell surface of leukemic cells but not on normal hematopoietic and non-hematopoietic cells. It is interesting that a number of these donor-derived antibodies recognized the U5 snRNP200 complex, a spliceosome component normally found inside cells. In AML however, the U5 snRNP200 complex is exposed on the surface membrane of leukemic blasts and can promote apoptosis in a FcR dependent way in the absence of cytotoxic leukocytes or complement. This potentially paves the way for novel tumor growth inhibitory therapy (AML-specific cytotoxic antibodies in patients with durable graft versus leukemia responses Marijn A. Gillissen, Martijn Kedde, Greta de Jong, et al., *Blood* 2017: blood-2017-02-768762; doi: https://doi.org/10.1182/blood-2017-02-768762i).

CHILDREN BORN SMALL FOR GESTATIONAL AGE, FIVE YEARS EXPERIENCE WITH GROWTH HORMONE THERAPY(Abstract) **Aim:** Recombinant Human Growth Hormone (rhGH) is an effective treatment for short children born small for gestational age (SGA) who fail to demonstrate catch-up growth by 2-4 years of age. These children usually don't have classical GH deficiency, but either low GH secretion or reduced sensitivity to GH. The goals of therapy are to achieve a normal height in early childhood and an adult height within the normal target range. We assessed the efficacy and safety profile in the first 5 years of rhGH treatment in ten SGA children. **Material and methods:** The study enrolled 10 SGA children (6 boys, 4 girls). All patients were given a mean dose of 0.35mg/kg/wk. and followed for a period of minimum 5 years (mean 5.68 yrs.). **Results:** The mean height expressed in standard deviations (SD) raised from -2.43 at diagnosis to +0.28 after 5 years. In the first 5 years of therapy there were no cases of diabetes mellitus or impaired glucose tolerance, 2 (20%) patients presented impaired fasting glucose, 1 (10%) patient developed hypothyroidism and 4 (40%) patients presented transitory subclinical hypothyroidism. Mean IGF-1 values were higher, but not exceeding +2DS. Conclusions: GH therapy is reasonably safe and effective in increasing linear growth in children born SGA who fail to have catch-up growth. Maximum height velocity was registered in the first year of treatment, 11.76 cm/year and declined in time. Adverse events due to GH treatment were no more common in the SGA population than in GH-deficient children. **Keywords:** SMALL FOR GESTATIONAL AGE, RECOMBINANT HUMAN GROWTH HORMONE.

Many children with short stature do show compromised adult height relative to mid parental height for age, sex, and population group (1). When children with short stature have been born with a low weight and/or length, they are classified as short associated with being small for gestational age (SGA). International Societies of Pediatric Endocrinology and the Growth Hormone Research Society, as well as the International Small for Gestational Age Advisory Board, recommended that the term refer to infants whose birth weights and/or lengths are at least two standard deviation

(SD) units less than the mean for gestational age (1,2). According to this definition, approximately 3%-10% of newborns are considered SGA. While most of these infants undergo catch-up growth, 10%-15% remain small for their age at the age of 2 years. In addition to short stature, SGA infants may be predisposed to altered body composition and (in adult life) hypertension and cardiovascular disease (1, 3). Data from epidemiological studies indicate that children born SGA are also at increased risk of insulin resistance and type 2 diabetes in adulthood (1). There is now evidence for an increased prevalence of metabolic syndrome among adults who were born SGA (4). Important is that their height, weight, and body mass index are closely monitored to prevent excessive weight gain, as children born SGA who catch up in weight and height are at a higher risk than those without catch-up (5). In summary, SGA is associated not only with shorter than average height, but also with potential health disadvantages, such as reduced body fat and a lack of appetite as compared with individuals who were not born SGA; there is also an increased prevalence of metabolic disorders in later life among patients born SGA as compared with those born AGA. Being born SGA is associated with lower cognitive ability in mathematics and reading comprehension and with more emotional, conduct, and attention deficit hyperactivity disorders. A relatively recent study (6) showed low values of psychomotor development and IQ in 60 children born with intrauterine growth restriction (IUGR) aged between 3 months and 16 years. The Wechsler Intelligence Scale for Children scores showed a slight worsening. The impact on the IQ seems to be inherent to the condition of being small at birth and not to the growth rate. In healthy people, Growth hormone (GH) and Insulin-like growth factor (IGF) interact to regulate growth. In utero, IGF-I, IGF-II and insulin are the key factors in regulating fetal growth, with GH having little effect. Postnatally, the contribution of IGF-I becomes more important than that of IGF-II, and neonates with growth restriction have lower IGF-I levels than neonates with a normal growth. Importantly, it has been reported that a high endogenous GH secretion significantly increases the IGF-I levels in short GH-sufficient neonates born SGA at 3 days postnatally as compared with AGA controls (7). This is evidence for a functionally activated GH-IGF-I axis in SGA neonates (8). Approximately 60% of the children with a persistent short stature who were born SGA have an abnormal GH secretion and reduced IGF levels (9). Although children with a short stature who were born SGA frequently have GH levels lower than normal, most are not usually classified as being GH deficient by recognized criteria. The status of the GH-IGF axis at birth or in early postnatal life is not predictive of later growth, and therefore hormone measurements in the SGA infant or child are not indicated in routine care. Early evaluation of short children born SGA is recommended, and those under 2 years of age with a current length below −2.5 SD should be referred for evaluation. Over the last 30 years, several recombinant human growth hormones (rhGH, Somatotropin) products have been approved for the treatment of children with growth disorders associated with short stature, and multiple studies, both observational and randomized, have established the efficacy and safety of rhGH products. 10% of SGA babies fail to show catch-up growth despite

good nutrition after birth. They continue to grow at a percentile that is lower than - 2 SD and their target height percentile. SGA babies with birth length more than -2 SD below the mean have a 7 times higher risk of having short final height, and those with a birth weight more than -2 SD below mean have a 5 times higher risk, indicating that birth length has greater influence on final height than the weight. Of the infants who do not show catch-up growth, 50% end up as short adults. They constitute 14 - 22% of short adults (10). Recombinant human Growth Hormone has been used to help short SGA children achieve catch-up growth. In July 2001, GH was approved by the US Food and Drug Administration for the long-term treatment of growth failure in children who are born SGA and do not achieve catch-up growth by 2 years.

MATERIAL AND METHODS

Observational study on ten pre-pubertal children (Tanner stage I) born SGA with growth disturbances defined as current height standard deviation score (HSDS) \-2.5 (and parental adjusted SDS \-1) for chronological age and sex (tab. I). Patients were treated with rhGH 0.035 mg/kg/day by subcutaneous injection in the evening. The objectives include an evaluation of efficacy through changes in height parameters; measurement of rhGH-induced serum markers IGF-I; incidence and adverse events (AEs).

TABLE I.

Data from the first 5 years of rhGH therapy

Parameter	Baseline	1 year	2 yrs.	3 yrs.	4 yrs.	5 yrs.
Chronological age (yrs.)	6.29	7.29	8.29	9.29	10.29	11.29
Bone age (yrs.)	4.05	4.75	5.56	7.15	9.3	11.05
Mean IGF-1 values (ng/ml and SD)	77.5 (+0.24)	305.38 (+1.49)	258.71 (+1.54)	329.85 (+1.26)	412.44 (+1.47)	476.55 (+1.85)
Height (SD)	-2.43	-1.37	-0.91	-0.68	-0.43	0.28
Growth velocity (cm/yrs.)	-	11.76	9.24	8.16	7.68	6.24

Another objective was to evaluate the long-term effect of rhGH treatment on the development of diabetes mellitus in short children born SGA. Height was measured in cm and HV calculated. HSDS and HV were assessed at baseline and at 6-month intervals. To determine bone age, X-rays of the left hand and wrist were obtained at baseline and every year thereafter. IGF- was measured at screening and at every 6 months thereafter. Fasting plasma glucose, 2-h OGTT, HbA1c were measured at baseline, and annually thereafter. All AEs were recorded at each visit and their incidence was reported. Physical examinations and vital signs were performed at each visit. Hematology, blood chemistry, thyroid function tests - free thyroxine (FT4) and thyroid stimulating hormone (TSH) levels-, lipids were assessed at baseline, at every 6 months. Paired t tests were used to calculate p values, with statistical significance defined as $p<0.05$.

RESULTS

Body height increased steadily throughout treatment period; the mean height standard deviation score improved by 2.71, from -

2.43 at baseline to +0.28 at 5 years of therapy; the changes in HSDS decreased with time (fig. 1). Mean height velocity was maximum in the first year (11.76 cm/year), decreasing in the second (9.24 cm/year), third (8.16 cm/year), fourth (7.68 cm/year) and fifth year of treatment (6.24 cm/year). Growth velocity decreased slightly but remained higher than at baseline ($p<0.0001$) (fig. 2).

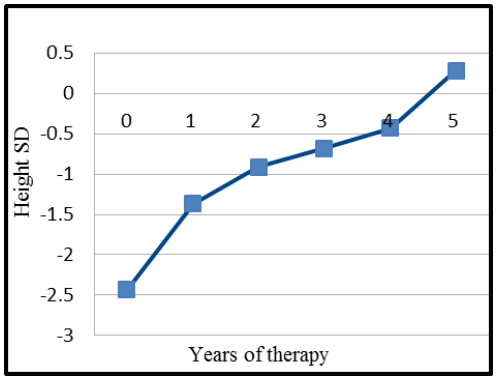

Fig. 1. Height SD during first 5 years of rhGH therapy

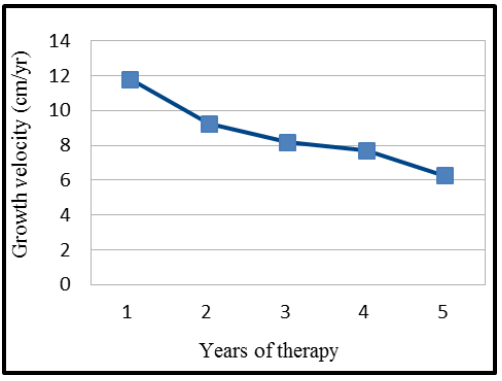

Fig. 2. Growth rate during the first 5 years of rhGH treatment

Chronological age at therapy initiation varied between 4 and 12 years (mean 6.29 yrs.). Bone age at diagnosis was late by a mean value of 2.24 years, decreasing after 5 years of treatment at a mean value of 0.24 years (fig. 3). IGF-I serum level indicated that at baseline most patients had low (\-2 SD) IGF-I levels. During the treatment IGF1 has normalized and even has risen above normal. Mean IGF-1 values were higher than normal range after five years, but not exceeding +2DS (fig. 4).

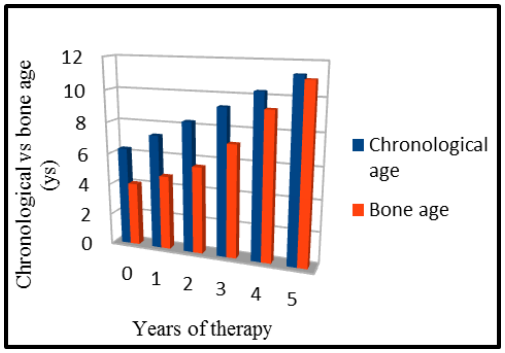

Fig. 3. Evolution of bone age during first 5 years of therapy

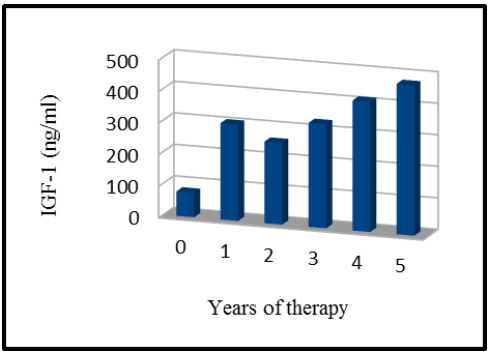

Fig. 4. IGF-1 values during first 5 years of treatment

In the first 5 years of therapy there were no cases of diabetes mellitus or impaired glucose tolerance (glucose between 140-200 mg/dl at OGTT; normal values of HbA1c). Two (20%) patients presented impaired fasting glucose (fasting glucose

between 100-126 mg/dl). One (10%) patient developed hypothyroidism. Four (40%) patients presented transitory subclinical hypothyroidism (elevated TSH, normal FT4 values, no clinical signs) (fig. 5).

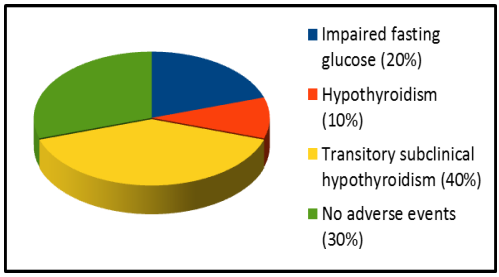

Fig. 5. Adverse events during first 5 years of rhGH treatment

DISCUSSION

Early initiation of rhGH therapy has as result the complete recovery of statural deficit in 5 years, according to growth prognosis calculated by parental heights. Growth response to GH treatment of non-GH deficient SGA children was done by Zegher et al (11). The analysis revealed that GH was an effective treatment for normalizing short stature in non-GH deficient SGA children during early childhood and puberty. According to consensus guidelines, a change in HVSDS of more than +0.5 within the first year of GH treatment is a growth response (1). In a large international cohort of children born SGA, HVSDS had to be at least +1 after the first year of treatment for patients to be eligible to continue with therapy; therefore, all patients regarded as responders in the present study achieved a growth response as defined in the consensus guidelines (3). Analysis of data from KIGS (Kabi-Pharmacia International Growth Study database) (12), which included data from 613 children born SGA who failed to manifest spontaneous catch-up growth, revealed that the age at which GH therapy was started was second only to dosage as the most important predictor for response. During the 1st year of therapy, the response to GH correlated negatively with age at initiation of treatment. The treatment response during the 2nd year was best predicted by a three-parameter model: HV during the 1st year of treatment, age at the start of treatment, and rhGH dose. The study confirmed the superior efficacy of beginning therapy earlier and with higher doses of rhGH treatment as compared with delaying therapy or using lower doses (3, 4, 13). An independent, international SGA Advisory Board (2) and the 2006 consensus meeting of the International Societies of Pediatric Endocrinology and the Growth Hormone Research Society (1) both developed a consensus for management of short children who were born SGA. Therapy was recommended for short children born SGA who do not manifest spontaneous catch-up growth by the age of 2-4 years. It was concluded that therapy with GH is effective and safe. The International SGA Advisory Board (4) recommended the initiation of rhGH therapy at 0.48 mg/kg/week; Long-term continuous treatment is effective, even at a dose of 25 µg/kg/day. Bone age for skeletal maturation should be done, although it is not a good predictor of adult height. Our study limitations, like many others, include the lack of a control group and the age of patients when rhGH treatment was initiated. However, the clear treatment benefits observed in most patients' deficiency.

CONCLUSIONS

In our study GH therapy was reasonably safe and effective in increasing linear growth in children born SGA who fail to have catch-up growth. Maximum height velocity was registered in the first year of

treatment, 11.76 cm/year and declined in time. No severe adverse events were registered. No malignancies were observed to date.

EDITORIAL

SURGICAL ONCOLOGY - THE MULTIDISCIPLINARY TEAM (MDT) IMPORTANCE

"Surgery has undergone many great transformations during the last fifty years, and many are to be thanked for their contributions – yet when we think of how many remain to be made, it should rather stimulate our inventiveness than fuel our vanity".

Sir Percival Pott, 1714-1788, Surgeon,
St. Bartholomew's Hospital, London, UK

Cancer is in our days a multidimensional and multifactorial reality. Hanahan and Weinberg in their paper called "*The Hallmarks of Cancer*" showed that to progress and to become a threatening disease, the tumor cells need to relate to different genetic and molecular events (1).

All over the world, cancer is the second leading cause of death after cardiovascular diseases, and a substantial amount of resources are allocated to provide patient care, rehabilitation, education and cancer research. A rapid development of Oncology is associated with a new specialties evolution.

Oncological surgery means specific technique and approach to tumorous conditions. It is technique adapted to, and based upon our knowledge, of tumor biology.

Surgical oncology covers a much wider field than oncological surgery: the role of the surgeon in the tumor treatment. Apart from the surgical act, the activities are basic research, prevention and many other fields (2). Surgery is the oldest oncological discipline. The mantra of the cancer surgeon was that increasingly radical surgery, would enhance cure rates. Preservation of form, function, and quality of life, without compromising survival, is the new mantra. Today's surgeons, no longer the uneducated technicians of history, are highly trained medical professionals and together with oncologists, radiologists, scientists, anesthetists and nurses, have made cancer surgeries routine and save (3).

From a historical perspective, surgical approaches to cancer existed far before the discipline now known as "Surgical Oncology". The surgical treatment of cancer originated as an approach focused on radical and debilitating tumor resections and extended lymphadenectomies. These "bigger is better" procedures, are focused on removing all loco-regional tissues, including those with any potential local extension. Much has changed over the last several decades that has made surgical oncology an academic and evidence-based specialty. What has led to modern surgical oncology, being the field it is today, is the development of large prospective databases, the design and participation in randomized controlled trials, and the translational research, that has ushered specialized and customized patient cancer therapy effective (4). Surgical oncology is more of a cognitive, than a technical surgical specialty. Apart from a small cluster of index operations, such as regional pancreatectomy, limb salvage and retroperitoneal sarcoma surgery, isolated limb perfusion, and

multisegment liver resection, most of the surgical procedures that are performed by surgical oncologists, are like those performed by a surgeon not oncologically trained**.** What frequently differentiates these two types of surgeons is not merely knowledge about how to do a specific operation, but an awareness of how and when to do that operation; that is, the cognitive knowledge of contemporary multimodality cancer care (5). Surgical Oncology is a consumptive surgery that requires new technologies and high human resources. In a study where the oncologic surgeons were surveyed, almost 94% of the persons, included in the study had experienced one occupational symptom, within the past 6 weeks and 28% reported having an occupational injury at some time, during their career. The surgeons manifested nonspecific symptoms such as fatigue, general physical discomfort and the cervical spine pain (38%) that were associated with prolonged operations concluding that is necessary to improve human engineering in the operating room as an important strategy for reducing occupational injury (6).

The unique difficulty for the surgical oncologist comes with understanding the balance between surgical and non-surgical therapies for solid tumors. A practitioner must to be familiarized with high variety of treatment modalities and should be able to select the right patients for surgery at the right point in the evolution of the disease. Beside that un optimal surgical treatment should be given to a high level of proficiency, that will ensure the best clinical outcome for the patient (7). In our days, when talking about solid tumors, surgical resection represents the most important possibility of treatment, giving the only hope of cure for patients in most cancer. Over the past several decades the field of Surgical Oncology has become much more defined, resulting in important contributions to the diagnosis and management of a wide variety of cancers. When searching on the Medline data base references to 'oncology' from 100,000 results more than 15% contain the additional reference term 'surgery' (8). Fundamental research in oncology, also being a major task, a continuous challenge for the surgical oncologists, likewise means intensive contacts with other specialties; multidisciplinarity is essential (fig. 1).

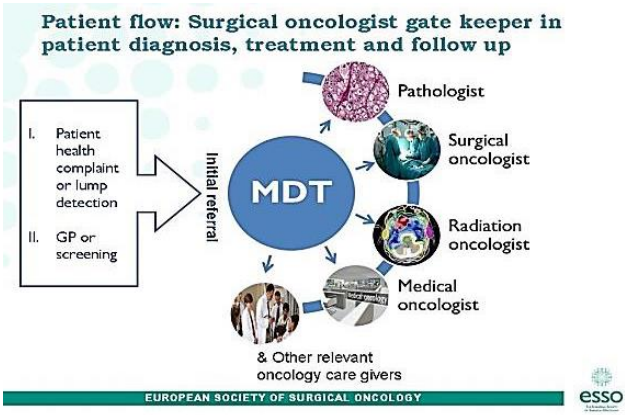

Fig. 1. MDT- multidisciplinary team (https://worldspanmedia.s3.amazonaws.com/media/esso/gallery/page-content-items/mission-vision.jpg)

With the increasing incidence of cancer and growing complexity of cancer care, multidisciplinary teams have the potential of improving the quality of life and increasing survival of cancer patients. Although there are several challenges to the success of the multidisciplinary teams, continuous commitment and support will ensure that multidisciplinary teams achieve its full potential in delivering effective and efficient, cancer care. Controversies, which are inevitable within a team that is striving to reach decisions concerning complex situations, thus require a variety of approaches for dealing with them when they occur (9).

Multidisciplinary team meetings are also known as tumor boards, multidisciplinary cancer conferences, multidisciplinary case reviews, or multidisciplinary clinics, in different health care systems. These different terms may represent the variations in the organizational structure, membership, approach, focus, and the decision processes of these meetings (10). Multidisciplinary team model in cancer care was introduced and endorsed to ensure that care delivery is consistent with the best available evidence. Over the last few years, regular meetings have become a standard practice in oncology and gained the status of the key decision-making forum for patient management. Every cancer case must to be discussed at a multidisciplinary conference where specialists involved in diagnosis and management are present. The role is to provide diagnostic, staging, and treatment-related elements that will be represented by the personalized therapeutic plan. A fully trained general surgeon is considered to have sufficient technical skills associated with knowledge and experience to approach the solid tumor and to provide the best medical care to the patient. Simulation and virtual simulation are very important steps to enhance technical skills and to improve operating room performance (11).

Performance in surgery depends on non-technical skills such as decision making, patient factors and technical skills of the healthcare team. Technical factors that affect decision making include the information about patients, robust CT and video-conferencing equipment, a minimum dataset with expert review of radiological and pathological information, implementation and recording of the MDTs decision. Non-technical factors with an impact on decision making include consensus on decisions and communication with patients and primary care, open discussion, attendance of team members at meetings, leadership and teamwork. To raise the quality of care for patients with cancer, a strong decision making based on a factors optimization is required (12).

The advantage of a MDT, is that the patient could benefit of different specialties consultation during one single visit. Between 4 and 45% of the patients discussed at the MDT meeting occurred changes in diagnostic. The results after a MDT case evaluation showed changes in staging and diagnosis, initial management plan of the patient, higher rates of treatment and a shorter time to starting the treatment after diagnosis, a better survival and accordance with international guidelines. Still is only a little evidence that show the impact of MDT over the clinical outcome of the patients (13).

Multidisciplinary meetings (MDMs) make sure that comprehensive treatment plans for patients with cancer are made. Although many doctors attend MDMs and contribute to the decision-making process, only a few will become involved in a patient's care after the team meeting. An issue that is debated all over the medical filed is represented

by the legal aspect of these meetings. If a patient wished to recover damages, all doctors present at the meeting would be personally accountable for decisions related to their area of expertise ant that is why doctors should be aware of the legal implications of their participation meetings (14).

The MDT activities are confronting with some important issue that many times are difficult to be corrected such as: non-uniform access to specialist care, frequent reporting of inadequacies in cancer services, disjointed referral system, large variations in frequency of individual treatments used, caseload for doctors treating cancer, and patient survival. Resources like staff time, founding, evidence of MDT effectiveness, communication, administrative support, clinical trials and clinical outcome had to be continuously evaluated to ensure a good efficiency of the MDMs (15).

Cancer treatment nowadays needs a multimodal approach, based on a MDT activity. That means, neoadjuvant treatment, surgery and where it seems to be necessary even an adjuvant treatment. It is not an option to stay still. The major advances in radiation and medical oncology of the past few decades have changed the face of cancer treatment forever. Tumors previously thought unresectable with curative intent, can now be brought to potentially curable surgical resection using neoadjuvant strategies. Adjuvant radiotherapy following a conservative surgical procedure allows the patient to be spared from the morbidities associated with radical surgery or radical radiotherapy, where higher doses of radiation are administered. It is likely that the use of adjuvant radiotherapy will increase in the future, together with an increase in usage of chemotherapy and/or novel biological agents, especially within the context of multimodality management of cancer. In this scenario, the place of multi-disciplinary approach is especially important, with input from specialists such as oncologists (surgical and non-surgical), radiologists and pathologists at the outset, so that the optimal management decision is made before embarking on treatment (16). With advances in the basic sciences, newer therapies have emerged in the treatment of cancer. One of the key developments was the use of antibody therapy. Chemotherapy treatments for cancer have advanced considerably in the past several decades. In addition, supportive measures have also improved significantly, and chemotherapy today is much better tolerated than it was only a decade ago. There are more treatment options, more effective therapies, and new ways of delivering drugs preferentially to the tumor.

Surgeons with oncological practices need to bring their personal drive, dedication and intellectual rigor to the cancer trials and research teams. By integrating into local, regional, national and international organizations, surgical oncologists will continue to enhance the quality and success of cancer trials and studies that change clinical practice and benefit individual patients and populations (17).

The future of surgical oncology is not simply to remove more body parts, but to better select the best treatment for each individual patient.

TOPICALITIES IN THE SUDDEN UNEXPECTED DEATH SYNDROME IN INFANTS (Abstract): Sudden Infant Death Syndrome (SIDS) represents the third cause in postnatal mortality. The pathogenesis is multifactorial. SIDS victims can present sign of preexisting chronic asphyxia, persistent increase in dendritic spine and delayed maturation of synapses in medullary respiratory centers, if a decreased reactivity of 5 hydroxytryptamine 1A (5-HT1A) and 5-HT2A in the dorsal nucleus of the vagus, solitary nucleus and ventrolateral medulla. SIDS is an exclusion diagnosis, so that inexplicable SIDS is the accepted term. The objective of this report is to present current data about the pathogenesis oh this syndrome and the medico-legal measures applied in preventive and curative aim. The "face-up" sleeping position has cut in half the SIDS frequency. In conclusion, the infant sleep studies represent an important line for the future research to provide sufficient explanation of the sudden death in these infants. **Keywords**: SUDDEN DEATH, PATHOGENESIS, CLINICAL EVENTS, MEDICO-LEGAL MEASURES.

The sudden infant death syndrome (SIDS) is the third cause of postneonatal (1 month to1 year) mortality in industrialized countries (1). The phrase unexpected infant death syndrome (UIDS) is preferred, as it includes all cases of SIDS, defined as the brutal death of a child under 1 year, installed in full health and unexplainable even after the postmortem investigations, including a full and scientific necropsy, extended complementary examinations, full anamnesis and clinical examination and a detailed inquiry at the tragedy scene. SIDS is an exclusion diagnosis, as a series of non-SIDS causes (18.6%) were identified within the UIDS, such as: infections (7.2%), congenital cardiopathy (2.7%), child abuse (2.5%), genetic and metabolic diseases (2.1%) (2). In consequence, SIDS is classified in explainable SIDS (UIDS) and unexplainable SIDS. The SIDS incidence varies between 1.5-2‰ live births in 1994 and 0.45‰ live births in 1999, representing 15% of the pediatric deaths (3). The maximum frequency is recorded between the ages of 2 and 4 months and during the winter months; in 53% of the cases, the infant with SIDS sleeps in the same bed with at least 2 other persons and associates a low social-economic status (4).

ETIOPATHOGENY

Due to the definition from 1970 given by Beckwith (2), SIDS was considered as a causeless death. Subsequently it has been observed that not all the cases of sudden death were normal from the anatomopathological point of view, but they associated brain abnormalities original from the intrauterine life, which can determine sudden death in a vulnerable period after birth. In 1972 the hypothesis of the triple risk in SIDS was released, including: general vulnerability, the risk specific to the age and precipitation factors (5). The most important hypotheses in SIDS are the respiratory one (apnea), cardiac one (arrhythmia) or visceral dyskinesia (glottal spasm and/or gastro-esophageal reflux) (6). It has been demonstrated that the autonomous system (respiratory, cardiovascular, upper digestive) participates in all these hypotheses, even if the arrhythmogenic cardiac dyskinesia, as the leading cardiac system is under strictly autonomous control (7).

The subsequent ethipathogenic concepts assert multifactorial involvement in the SIDS, as follows: genetic factors, infant risk factors, maternal risk factors and environmental factors.

The *genetic factors* are demonstrated through the new discoveries in the field of molecular genetics and the identification of genetic polymorphism of the victims of sudden death. Almost two thirds of the cases have signs of preexisting chronic asphyxia and higher expression of the vascular endothelium growth factor (VEGF) in the cephalorachidian fluid. Brain abnormalities in infants with SIDS consist of the significant increase of the denditric extensions and late maturation of synapses in the medullary respiratory centers, as well as the decrease in the immunoreactivity of the receptors of 5 hydroxytryptamine 1A (5HT2A in the vagus nerve, of the solitary nucleus and of the ventrolateral medulla, and increases were discovered in the brain periductal grey matter, along with gliosis (8).

The hypoplasia of the medullary arcuate nucleus, an important cardiorespiratory center was discovered in over 50% of the SIDS cases. This can associate with alterations of other structures of the brain stem, such as hypoplasia of the Kolliker parabrachial area and of the reticular formations of the respiratory system. Rarely cases of SIDS were reported in relation to the neuronal hypoplasia and immaturity of the hypoglossal nucleus responsible for the deglutition alteration (9).

The postmortem genetic studies discovered genetic differences including defects of the sodium channels, serotonin-transporters and abnormalities of the genes of the autonomous nervous system, the C4 complements and IL-10. The long QT syndrome is associated with the sodium channels gene (SNC 5A) defect. Over 100 mutations were identified, of which over 30 are associated with the prolonged QT syndrome (10).

Molecular genetic studies in the SIDS victims identified mutations from the early embryological development of the autonomous nervous system. The relevant genes are MASH 1 (mammalian achaetescute homolog 1), BMP 2 (bone morphogenetic protein 2), PHOX 2b (paired-like homeobox 2b), RET (rearranged transfection factor), ECE 1 (endothelin converting enzyme 1), EDN 1 (endothelin 1), TCLR 3 (T cell leukemia homeobox) and EN (engrailed 1). The mutations of these genes can affect the cardiorespiratory control, but up to the present the genotypic differences between the SIDS victims cannot be related

to any type of defined clinical phenotype, putting to the issue the interaction between the genes and the environmental risk factors (11).

The risk factors for SIDS specific to the infant are the male gender, age between 4 and 6 months, low weight upon birth and prematurity.

The maternal risk factors for SIDS are age under 19 years, active smoking, which doubles the risk for sudden death, the use of illicit drugs, short time between births and limited or delayed prenatal cares (12).

The environmental risk factors for SIDS are the ventral position during sleep, passive smoking, high temperature, humidity, the cold season, sleeping in the same bed with someone else and poverty (13).

FORENSIC MEDICAL MEASURES IN SIDS

The prior clinical events are determined by the synergy of the changes in the respiratory rhythm on the heart rhythm. Originally, 2-3 days before the fatal event, the infant has tachycardia, profuse sweats, and subsequently bradycardia and low blood pressure. These elements suggest an abnormal sympathetic and parasympathetic activity secondary to the dysfunction of the respiratory rhythm on the heart rate, like the state of shock, when sympathetic excitation (profuse sweats, tachycardia, increase in the blood pressure) happens in the compensatory stage, and sympathetic inhibition (bradycardia, low blood pressure) happens in the decompensating stage, resulting in the loss of tissue perfusion and death. Abnormalities could emerge in the brain structures controlling the variations of the respiratory rhythm, heart rate and the blood pressure values during sleep (cerebellum, medullar central surface, Raphe caudal nucleus, the inferior olive and the fastigial nucleus of the cerebellum). It can be speculated that SIDS is the result of a decrease in the uncompensated blood pressure, because of cerebellum lesion (14).

The forensic medical measures in SIDS are different if applied in curative or preventive purpose.

At the site of a SIDS case firm administrative and medical measures are imposed, which in certain countries are enacted through circular letters of the Ministry of Public Healthcare, mentioning: the direct phone line with the reference regional centers, the manner of urgent transportation of the body of the deceased infant by some medical team or competent personnel in a vehicle authorized by the police to the morgue. The body is transported to the forensics department, after which the police will carry out an investigation, if there are suspicious circumstances of the decease, the clinical examination reveals abuse signs, the refusal of an autopsy, decease after 9 months of age, and if there have been any other deceases of family members in suspicious circumstances.

The main purpose of the medical actions is the detection of the cause of death, possibly in 50-75% of the cases = explainable sudden death (UIDS) and the determination of the risk in siblings, to answer the parents' question about what would happen to their other children. The etiological medical investigation includes a full physical examination of the deceased infant (weight, height, perimeters, tegument aspect, liver, spleen), X-rays (thorax, skeleton, cranium), biological sampling (intracardiac puncture – blood, suprapubic puncture – urine, lumbar puncture – CRL) for the bacteriological, virological, biochemical and genetic examinations. The anatomopathological

examination will perform numerous histological sections in all organs (15).

The SIDS relation with the risk of repetition in siblings is like the risk in the general population, the sporadic cases being more frequent than the family ones. Nevertheless, there are families with high risk of repetition of the sudden death, such as: several sudden deaths in the genealogical tree, sudden death after 1 year, the metabolic disease, hereditary vagus hyperreactivity, precarious social-economic conditions, abuse and bronchomalacia in autopsy. The major indications of exploration of the collaterals of a suddenly deceased infant, by means of a 48-hour hospitalization, are the following: clinical signs of gastro-esophageal reflux (GER), uncontrolled fear, family vagus field and congenital prolonged QT syndrome. The twin of a suddenly deceased infant runs a risk 22 times higher for SIDS because of identical infectious and environmental factors, rather than because of genetic factors. Consequently, the twin will be hospitalized urgently with his/her mother, for a clinical examination and paraclinical explorations to exclude infections, GER, vagus hypertonia and congenital prolonged QT syndrome (16).

The prevention of SIDS consists in the elaboration of guides comprising recommendations for a risk-free sleep of infants. The recommended position for sleep in infants is the supine position ("lying on the back face upward"), in a crib with a firm mattress, no pillow or cover, in a room with the temperature between 18 and 20° C. The result of this measure is the decrease in the SIDS frequency by 50% (17).

CONCLUSION

SIDS is a complex multifactorial entity, whose frequency can be decreased by adopting preventive measures for the infant's sleep. Of the multitude of the physio pathological mechanisms involved, the study of the infant's sleep if a research line for the future, to find out why some infants die in their sleep, as a functional respiratory and cardiac response to different stimuli in the external environment.

It is of great need to pay attention to the environmental risks factors and the maternal factors as well. Even though no matter how much you prevent it, SIDS still appears to infants, in many cases, the smoking, the drug addiction or alcohol consuming during the pregnancy or after birth can lead to SIDS.

Also, in addition, we consider that infants decease cases should be highly supported and funded by with the great help from pediatricians and other medical specialists.

To get close to the factors and mechanisms of SIDS, and to break down a vicious and pathophysiological circle that also happen to affect infant's siblings.

NEW DRUGS FOR LOWERING LDL-CHOLESTEROL (Abstract): LDL-Cholesterol (LDL-C) is a well-known risk factor for cardiovascular disease. Although statins are the mainstream treatment for lowering LDL-C level, additional LDL-lowering therapies are needed to reduce residual cardiovascular risk, especially in patients at very high risk, or with hereditary lipid disorders or statin intolerance. The proprotein convertase subtilisin/kexin type 9 (PCSK9) is a key regulator for LDL-Receptor activity and an attractive target for the treatment of hypercholesterolaemia. From its discovery in 2003, several therapeutic approaches to the inhibition of PCSK9 have been proposed. Monoclonal antibodies that bind to PCSK9 received marketing approval in 2015 (alirocumab and evolucumab) or are being evaluated in phase III trials (bococizumab). Many other molecules are in preclinical studies, phase I or II clinical trials. Another point of interest carefully investigated is the cardiovascular benefit of reducing LDL-C using these new molecules. High hopes are invested in them. **Keywords:** LDL-CHOLESTEROL, PCSK9 INHIBITORS, ALIROCUMAB, EVOLOCUMAB.

Low-density lipoprotein (LDL) is removed from the circulation mainly by hepatic uptake. LDL binds to the LDL receptor (LDLR) and the LDL-LDLR complex is internalized into clathrin-coated vesicles by endocytosis. In the endosomes, LDL is separated from its receptor. Further, LDL is degraded in the lysosomes and the LDLR is recycled for later reuse.

The proprotein convertase subtilisin/kexin type 9 (PCSK9) was identified in 2003 by Seidah et al. (1) and is a key regulator for LDLR activity. The major function of PCSK9 is the degradation of the LDLR (2). Secreted PCSK9 binds to the LDLR. When LDL-LDLR complex is formed, the PCSK9 is internalized together with it. The binding of PCSK9 to LDLR induces a change in LDLR conformation, avoiding normal recycling of LDLR to the plasma membrane and enhancing the LDLR lysosomal degradation (3). Consequently, it reduces the number of LDLR on the cell surface and the liver uptake of LDL, thereby increasing the plasma levels of LDL-C. As high LDL-C levels have consistently been associated with an increased risk of coronary heart disease,

PCSK9 is an attractive target for the treatment of hypercholesterolaemia. Recent data suggest that its involvement in lipid metabolism is even greater, PCSK9 having a role in triglyceride metabolism and triglyceride accumulation in visceral adipose tissue (4).

Several therapeutic approaches to the inhibition of PCSK9 have been proposed.

MONOCLONAL ANTIBODIES

The most successful approach was the monoclonal antibodies that bind to PCSK9 near the catalytic domain, interact with LDLR and hence inhibit the function of PCSK9.

Alirocumab (Praluent) and evolocumab (Repatha) are fully human monoclonal antibodies that specifically bind to PCSK9. In 2015 they received marketing approval from European Medicines Agency and the U.S. Food and Drug Administration. Bococizumab is a humanized monoclonal antibody that specifically binds to PCSK9 that is currently in phase 3 clinical trials.

Alirocumab and evolocumab are indicated as an adjunct to diet and maximally tolerated statin therapy for the treatment of adults with heterozygous familial hypercholesterolemia (HeFH) or clinical atherosclerotic cardiovascular disease, who require additional lowering of LDL-C. Evolocumab is also indicated as an adjunct to diet and other LDL-lowering therapies for the treatment of patients with homozygous familial hypercholesterolemia (HoFH) who require additional lowering of LDL-C.

The ODYSSEY Programme was designed to assess the efficiency and safety of alirocumab in a broad spectrum of patient populations. When alirocumab was compared with ezetimibe in patients at moderate to high cardiovascular risk with statin intolerance due to muscle symptoms, it was found that alirocumab reduced mean LDL-C by 45.0% *vs* 14.6% with ezetimibe ($p<0.0001$), with fewer skeletal-muscle adverse events *vs* atorvastatin (5).

When alirocumab was added to atorvastatin, it provided significantly greater LDL-C reductions *vs* adding ezetimibe, doubling atorvastatin dose, or switching to rosuvastatin and enabled greater LDL-C goal achievement (6). ODYSSEY Combo II compared the efficacy and safety of alirocumab *vs* ezetimibe, as add-on therapy to maximally tolerated statin therapy in high cardiovascular risk patients with inadequately controlled hypercholesterolaemia and again, alirocumab achieved significantly greater reductions in LDL-C compared with ezetimibe, with a similar safety profile (7).

ODYSSEY FH I and FH II assessed the long-term alirocumab treatment in patients with HeFH and inadequate LDL-C control on maximally tolerated lipid-lowering therapy. Patients without a history of cardiovascular events and those who had suffered a myocardial infarction or ischemic stroke were eligible to enroll in the study if their LDL-C levels were not at goal according to current guidelines for primary or secondary prevention. Patients received stable high-dose statin therapy with or without other lipid-lowering therapy (fenofibrate, ezetimibe). The study demonstrated that alirocumab reduced LDL-C levels from baseline by 57.9% (FH I) and 51.4% (FH II) *vs* placebo. Alirocumab was generally well tolerated, with consistent LDL-C reductions observed throughout the study. By doubling the antibody dose when LDL-C goal was not achieved on the starting dose, some 59–68% of patients achieved an LDL-C goal of <70 mg/dL (8). Alirocumab also reduced apolipoprotein B levels (by 54%, $p<0.0001$) and plasma Lp(a) levels

(by 20.5–30.3%) (9).

A major study, the ODYSSEY Long Term Trial, enrolled 2341 high-risk patients with HeFH, known coronary artery disease or coronary artery disease risk equivalent, in a randomized, double-blind, placebo-controlled trial. Eligible patients had LDL-C levels above 70mg/dL and were currently taking either high-dose statins or maximum tolerated dosages. Other lipid lowering therapies were also allowed. A post-hoc analysis of cardiovascular events that included a composite of death from coronary heart disease, nonfatal myocardial infarction, fatal or nonfatal ischemic stroke or unstable angina requiring hospitalization showed lower rates with alirocumab. Heart failure requiring hospitalization and ischemia-driven revascularization were not included as cardiovascular events in this post hoc analysis. When these events were included, the difference between groups was no longer significant (10). Therefore, a hope for an enlightening response is expected from ODYSSEY Outcomes (currently in the period of enrollment), an ongoing trial that is intended to provide an assessment of the cardiovascular benefit of alirocumab in approximately 18,000 patients over a period of 5 years.

The PROFICIO Programme was designed to assess the efficiency and safety of evolocumab. Comparing evolocumab with ezetimibe in statin intolerant patients due to muscle symptoms, it was found that evolocumab reduced LDL-C from baseline by 55% to 56% (corresponding to treatment differences: 140 mg sc q2weeks = Q2W dose, respectively 420 mg sc once monthly = QM dose) *vs* ezetimibe, with low incidence of muscle adverse events (12). Evolocumab also reduced Lp(a) levels by 22% to 27% compared to 1.7 - 5.8% in ezetemibe-treated patients. Of the evolocumab-treated patients at high risk, more than 75% achieved LDL-C <100 mg/dl compared with less than 10% of ezetimibe-treated patients.

When evolocumab was added to a guideline-recommended lipid-lowering therapy (10 mg atorvastatin, 80 mg atorvastatin with or without 10 mg ezetimibe, according to the patient's ATP III defined cardiovascular risk), percent reductions in LDL-C in the evolocumab group *vs* placebo were 48.5% in the group receiving atorvastatin 80 mg plus ezetimibe, 56.8% in the group receiving atorvastatin 80 mg and 61.6% in the group receiving atorvastatin 10 mg (13). The LDL-C mean reduction in evolocumab group *vs* placebo was 57%. There were also significant reductions from baseline in apolipoprotein B, Lp(a) and triglycerides, as well as 5.4% increases in HDL-C and 3.0% in apoA1. In patients undergoing moderate or high intensity statin therapies, the favorable effect of evolucumab *vs* placebo or ezetimibe in lowering uncontroled LDL-C levels was once again proven without a doubt (14).

RUTHERFORD-2 Study assessed the safety and efficacy of evolocumab in patients with HeFH and inadequate LDL-C control on maximally tolerated lipid-lowering therapy. Evolocumab achieved mean percent reductions of LDL-C of 60.2% (Q2W dose) and 65.6% (QM dose), compared to placebo ($p < 0.0001$). LDL-C <70 mg/dl was achieved by 68% of patients in the evolocumab Q2W group and by 63% in the evolocumab QM group, compared to only 2% in each of the placebo groups. Patients with receptor-negative mutations had a similar response to treatment compared to those with receptor-defective mutations or those with mutations in apolipoprotein B (15). TESLA study was conducted in pa-

tients with HoFH receiving stable background lipid-lowering treatment and not on apheresis. Evolocumab significantly reduced LDL-C by 30.9%. Patients with defective receptor mutation had the best response to treatment and had significantly higher reduction in LDL-C compared to those with single LDLR negative mutation (16).

Patients enrolled into a longer-term extension trial were re-randomized to the evolocumab plus standard therapy *vs* standard therapy alone without placebo control. 70% of patients were receiving background statin therapy. LDL-C was reduced by 61% to a mean of 48 mg/dL. Approximately 80% of patients had other cardiovascular risk factors including hypertension, diabetes, metabolic syndrome, current cigarette use, family history of premature coronary artery disease or familial hypercholesterolemia. The cardiovascular events (death, myocardial infarction, unstable angina requiring hospitalization, coronary revascularization, stroke, transient ischemic attack and heart failure requiring hospitalization) occurred in a 1% of the evolocumab group *vs* 2% of the standard therapy group (17). The FOURIER Study is ongoing to confirm this finding and to determine if adding a PCSK9 inhibitor to standard statin therapy with will further decrease cardiovascular events over long-term follow-up.

Very little data is available on efficacy and safety of bococizumab. In a phase 2b dose-ranging study of subjects with hypercholesterolemia on stable doses of statin, compared with placebo, bococizumab significantly reduced LDL-C levels across all doses (18).

GENE INHIBITORS

Several other agents inhibit the gene responsible for the synthesis of the PCSK9 protein. Antisense oligonucleotides looked promising after the initial preclinical studies, but two phase I trials were terminated and development of the drugs had not been continued. ALN-PCS is a small interfering RNA that inhibits PCSK9 synthesis. ALN-PCS02 was successfully tested in a phase I trial on healthy volunteers with raised cholesterol who were not on lipid-lowering treatment (19).

MIMETIC PEPTIDES

The catalytic domain of mature PCSK9 binds to the first epidermal growth factor-like repeat A domain (EGF-A) of the LDLR, while the C-terminal domain binds to cell surface proteins, including annexin A2 (20). In order to induce its internalization and degradation, PCSK9 binds to EGF-A domain of LDLR. A mimetic peptide, which mimics the actions of EGF-A, was demonstrated to competitively inhibit PCSK9-mediated degradation of LDLR in HepG2 cells. Mimetic peptides currently being investigated are: EGF-AB peptide fragment, LDLR (H306Y) subfragment and LDLR DNA.

SMALL MOLECULE INHIBITORS AND ADNECTINS

Small molecule inhibitors and adnectins targeting circulating PCSK9 are currently being developed. Orally administered small-molecule inhibitors may act by altering the sequence of PCSK9 auto-catalytic intracellular processing, PCSK9 secretion or LDLR interaction. SX-PCK9 and TBD are in preclinical studies (21). Adnectins are genetically engineered target-binding proteins, similar to monoclonal antibodies, including binding to targets with similar affinity and specificity, but differ in terms of sequence and lack of

disulphide bonds in their single-domain structure (22). The adnectin BMS-962476 has recently completed its phase 1 clinical trial and demonstrated good tolerability.

CONCLUSIONS

Multiple large studies have declared statins as the mainstream treatment for lowering LDL-C level, but additional therapies are certainly needed in order to reduce residual CV risk, especially in patients at very high risk, or with hereditary lipid disorders or statin intolerance. As we highlighted in this brief material, the addition of alirocumab or evolocumab to the existing lipid-lowering therapy has resulted in a significant, consistent and sustained reduction in LDL-C levels in patients with varying levels of CV risk. Even if at the moment the cardiovascular benefit of using these new drugs is still under investigation, high hopes are invested in them.

CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Cardiovascular (CV) risk constitutes a major concern in patients with dermatomyositis and polymyositis. A multicentric Danish study evaluated cardiovascular risk factors and coronary artery calcification (CAC) in 76 patients with idiopathic inflammatory myopathies (IIM) and a control group formed of 48 sex- and age-matched healthy subjects. Obesity was more frequent among IIM patients than in healthy individuals (33% in patients as opposed to 11% healthy individuals, $p<0.05$). Waist/hip ratios and serum tryglycerides also had higher values in patients with IIM compared to healthy controls ($p<0.05$). Arterial hypertension and diabetes mellitus were more prevalent in IIM patients ($p<0.05$). The extent of coronary artery calcification was estimated using the Agatston score which showed higher mean values in patients compared to controls but results did not reach statistical significance. It was shown that glucocorticoid therapy, higher age at the moment of diagnosis, high levels of glycated hemoglobin (HbA1c) and smoking status correlate with higher coronary artery calcification scores in patients ($p<0.05$). However, C-reactive protein levels did not asociate with a greater risk of CAC in the study group. Although not elucidating the mechanism behind increased CV mortality in IIM, the study brings to attention a series of important modifiable CV risk factors in patients with IIM. (Diederichsen L.P. et al. Traditional cardiovascular risk factors and coronary artery calcification in adults with polymyositis and dermatomyositis: a Danish multicenter study. *Arthritis care & research* 05.2015, doi : 10.1002/acr.22520. 67: 6 : 848-854).

EATING BEHAVIOR IN RESPONSE TO ACUTE STRESS (Abstract): Obesity is a medical and social problem with a dramatically increasing prevalence. It is important to take action since childhood to prevent and treat obesity and metabolic syndrome. Infantile obesity affects all body systems starting in childhood and continuing to adulthood. Understanding the impact of stressors on weight status may be especially important for preventing obesity. The relationship between stress, eating behavior and obesity is not fully understood. However, there is evidence that stress causes disorders in hypothalamic-pituitary-adrenal (HPA) axis, system that regulates both stress and feeding responses. Also, the response is different depending on the type of stressors. Chronic stress, especially when people live in a palatable food environment, induces HPA stimulation, excess glucocorticoids, insulin resistance, which lead to inhibition of lipid mobilization, accumulation of triglyceride and retention of abdominal fat. **Keywords**: EATING BEHAVIOR, FOOD INTAKE, ACUTE STRESS, CORTISOL, OBESITY.

In modern society, stress is everywhere and affects people of different ages, including children. It is difficult to define stress because it is so different for each of us. We can say that it is the generalized, non-specific response of the body to any demand for change. Stress can trigger many diseases, including obesity and other eating disorders (1).

Obesity is a heterogeneous disease that is difficult to treat (2,3). It is associated with risk factors for cardiovascular diseases and accelerated atherosclerotic processes, including hypertension, atherogenic dyslipidemia, atherosclerosis and structural and functional cardiac changes (1). The association of stress with obesity was suggested by Cushing's syndrome. Patients with this syndrome have upper body obesity, high levels of cortisol, atherosclerosis, glucose intolerance and hypertension (3).

Stress can be acute, short term or chronic, long-term. Stressors can be external (such as cold exposure, hunger, social stressors) or of internal cause (sleep deprivation) (4). When stress occurs, mechanisms are activated to maintain homeostasis. Homeostasis is the property of a system in which the variables are regulated so that internal conditions to remain stable and relatively constant. Homeostasis implies remaining stable by being the same, while allostasis is achieving stability through change. Allostasis is associated with

changes in food choice, appetite, energy storage and mobilization (4). This implies alteration in HPA axis hormones, autonomic nervous system, cytokines or a number of other systems. There is a close interaction between stress, allostasis, energy balance and eating patterns. Stress can influence human eating behavior in a bidirectional way (4).

Stress response. Allostasis is maintained in stress conditions by adaptive reactions originating in the central nervous system and in the periphery. Acute stress induces a fight-or-flight reaction with behavioral, autonomic and endocrinological changes. Heart rate and blood pressure are increased and energy spent on digestion and reproduction is minimized. Energy is saved for vital organs: brain, heart and muscle tissue to save life. So, in acute stress appetite and food intake are suppressed. However, there are situations of weight gain under stress. What determines direction of eating is not explained yet but HPA axis has an important role in both situation (4).

Stress response has two major components: the HPA axis and the autonomic nervous system (ANS) which encompasses the sympathetic and parasympathetic nervous system (fig. 1). Stress response depends on intensity, duration and type of stressor (5).

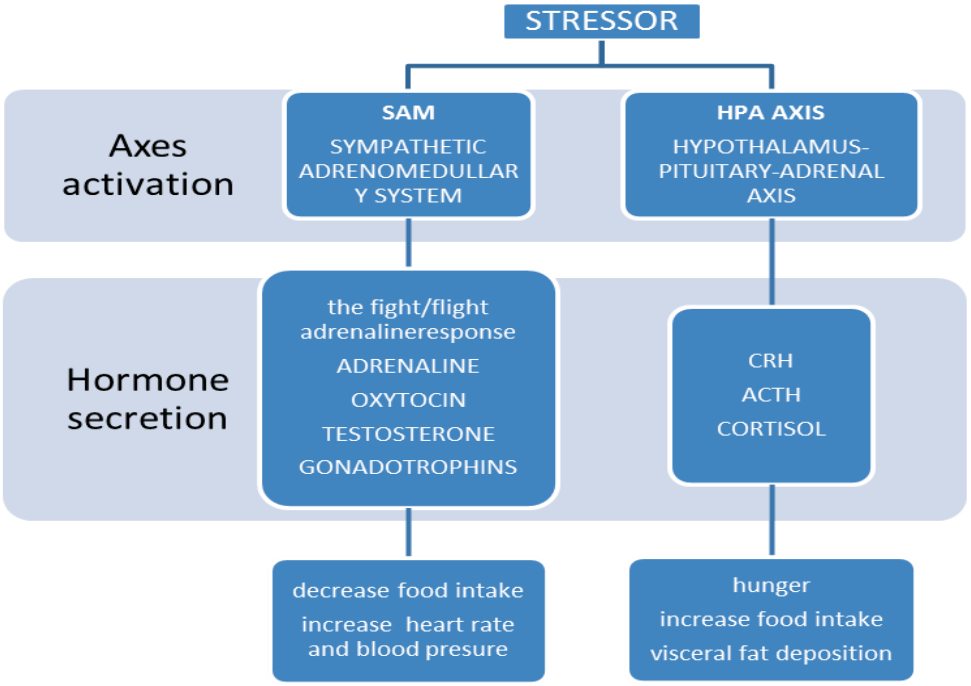

Fig. 1. Stress response (modified after Torres et al.) with two major components: SAM and HPA axis

There are two antithetical responses to stress according to the stressor type:

- ***Challenge stressor,*** a demanding but controllable situation that activates the sympathetic-adrenomedullary (SAM) system, with fight/flight response, which shuts

down digestion (6). For this type of stressor, the body has the resources to cope with.

• ***Threat stressor,*** for which the body does not have the resources to cope with or social stress (public embarrassment or failure, feeling defeated) activates HPA axis with cortisol release. Neurons of the paraventricular nucleus of the hypothalamus initiate stress response by corticotropin-releasing hormone (CRH) which modulates HPA axis. CRH stimulates the secretion of ACTH from the anterior pituitary. ACTH acts on the *zona fasciculata* of the adrenal cortex increasing cortisol secretion. Circulating cortisol has a negative feedback to the brain, limiting cortisol secretion, protecting the organism from prolonged cortisol exposure in chronic stress (6). It is known that cortisol stimulates hunger and feeding and visceral fat deposition. Glucocorticoids increase insulin secretion but has influence on orexigenic neuropeptide (NPY). Immune cells or adipocytes produces cytokines that may stimulate the HPA axis.

Eating behavior as a consequence of body response to acute stress.

To study the relationship between stress and eating behavior it is important to take into account the different types of stress. Stress can be acute (short term stressors) or chronic. Stressors can be physical (extreme temperatures, elevated sound levels, over-illumination, surgery, trauma), physiological (pain, hemorrhagic shock, intense exercise), chemical (acid-base imbalance, hypoxia), psychological or emotional (anxiety, fear, sorrow) and social (low social status, giving a speech, meeting new people, discrimination) (3).

Animal research. In animal studies all variables (type and intensity of the stressors, food offered) can be well controlled. Acute stress can be induced using stressors such as cold exposure, tail pinch, hunger, physical restraint, inescapable foot shock, exposure to a socially dominant member of the same species (6,7). Rats can be used for studying the effects of acute stress in a controlled laboratory setting with accurate evaluation of food intake. Stressors of different intensity can be used (6,7). Also, another factor is the type of food offered: commercial food for rodents (rat chow) or highly palatable food (sweetened milk). In rats, stress can lead in some cases to increases but mainly to decreases in food intake (6,7). The severity of stress is also very important. A severe stress is associated with a decrease in food intake. Moderate and mild stressors also lead to a decrease in food intake but increase the ingestion of highly palatable food (5,6,7).

According to the intensity and type of stressors the effect was either a decrease in food intake in rats exposed to acute physical stress (ex. pinch tail), or increased food intake after exposure to social stress (exposure to a socially dominant member of the same species, resident-intruder paradigm or social defeat), especially when offered a calorically dense diet (6). The last situation reproduces the modern society with numerous stressors, especially social stressors, and exposure to energy dense, highly palatable food.

Most studies highlight that stress reduces food intake in rodents, unless palatable food is given during the stress period. Also, administration of glucocorticoids increases food intake. Adrenalectomy reduces food intake, while subsequent corticosterone replacement normalizes it (3).

Human studies. Human studies confirm ingestion of palatable foods in response to stressful situations. Association between stress, comfort food and obesity is

complex. In humans it is difficult to differentiate the emotions because it could be intricate (6). Human studies show that stress decreases food intake in 30% of cases while most of subjects, 70%, increase their food intake with preference for palatable food (7,8). In modern society, a palatable food environment, it is more likely for people to increase food intake in stressful periods. Also, they will choose high calorie foods to cope with stress.

Stress reactivity has been studied in people with eating disorders (bulimia, anorexia and binge eating disorder - BED). Subjects with BED had either greater basal cortisol or greater cortisol reactivity (6,9).

Stress can be induced in laboratory conditions with the Trier Social Stress Test (TSST). After inducing stress with TSST subjects with high cortisol levels were likely to eat more calories, especially calorically dense food. On the control day there were no difference between high and low cortisol reactor groups (6). Another study compared a similar threat stressor to a positive challenge stressor (identical tasks but with positive feedback from the audience). The "threat" condition stimulated greater food intake, particularly of highly palatable food than the "challenge" condition (10,11). The relationship between cortisol and food intake in humans may also involve the effects of glucocorticoids on Neuropeptide Y (NPY), CRH, leptin as well as opioid and endocannabinoid signaling (12,13). Through multiple mechanisms, excess glucocorticoids determine insulin resistance. Even though cortisol causes hyperinsulinemia, this high insulin level does not affect plasma glucose concentration because of insulin resistance.

Stressors stimulate HPA axis and interfere with the reward system. Under stress conditions the mesolimbic dopaminergic system is activated and increased CRF secretion is stimulated. Food and drugs of abuse can stimulate similar pathways in the nervous system, including the dopaminergic and opioidergic systems. As well as drugs, hyper palatable foods alter CRF, GC and noradrenergic activity and increase sensitization of reward pathways which influence preference for addictive substance and hyper palatable foods and increases craving and intake. Repeated stimulation of the dopaminergic reward pathways may trigger neurobiological adaptions that may promote progressively compulsive behavior (4, 16)

Repeated stimulation of the reward pathways through highly palatable food may lead to neurobiological adaptations that determine overeating characterized by frequent drive to initiate eating. Opioid release increases palatable food intake and palatable food sustains opioid release. When stress becomes chronic, highly palatable food may appear to be "addictive" because the body is using food for coping with stress (4, 13, 14)

CONCLUSIONS

Our analysis of the literature studies revealed that the impact of stress depends on the intensity and type of stressors: acute or chronic. It involves multiple pathways, molecules and receptors. An important role is played by HPA axis which interferes with the reward systems. Repeated stimulation of the reward pathways through highly palatable food leads to overeating because of the neurobiological adaptations. Also, palatable food can lead to opioid release which in its turn increases the palatable food intake. Palatable foods can activate the brain reward system, so repeated stimu-

lation of the reward pathways through highly palatable food may lead to overeating with frequent drive to initiate eating. Moreover, the exogenous factors (nutritional) have a pro-obesity action by increasing the caloric intake determining energy imbalance. Additional studies are needed to understand the complex relationship between stress, alterations in HPA activity and obesity because in humans it is difficult to differentiate the emotions because it could be intricate.

ADHD (ATTENTION DEFFICIT HYPERACTIVITY DISORDER) – A TROUBLING ENTITY, SOMETIMES PERPETUATING DURING ADULT LIFE (Abstract): Attention deficit hyperactivity disorder (ADHD) is considered a neurologic development disorder resulting in impairment of attention and inhibitory control, manifested as attention deficit, hyperactivity, impulsiveness; symptoms should develop between age six and twelve and have to persist for more than six months. Approximately 30-50 % of the diagnosed cases are manifesting the disorder during adulthood and 2.5-5 % of the adults are suffering of ADHD. Genetics are important factors in ADHD, being involved in 75 % of the cases, as well in the persistence of ADHD during adult life. Three subtypes of ADHD are described – one in which is predominating the attention deficit, one with predominant hyperactivity and impulsiveness and a third combined subtype. Diagnosis criteria in ADHD are established by the American Psychiatric Association (DSM criteria) and by World Health Organization. Differential diagnosis is mainly considering bipolar disorder and borderline personality disorder. Management of ADHD is including behavioral therapies and medication, alone or combined. Stimulant medications such as amphetamine represent the therapy of choice, being effective in 80 % of the cases. New data are underlying the need for following up of the cases during adulthood, since the risk for development of psychiatric conditions such as depression, anxiety, as well as the suicidal behavior is higher than in the general population. **Keywords**: ADHD/ATTENTION DEFICIT HYPERACTIVITY DISORDER, HYPERACTIVITY, IMPULSIVENESS.

DEFFINITION, GENERAL FEATURES

Attention deficit hyperactivity disorder (or hyperkinetic disorder) is considered a neurologic developmental disorder in which are present problems of executive functions, like attention control and inhibitory control which are generating attention deficits, hyperactivity or inappropriate impulsiveness (related to age) (1,2).

Diagnosis is established only when symptoms are lasting for more than six months and are appearing between age six to twelve.

In 2013 World Health Organization estimated 39 million people affected by the disorder; 3-5 % of children are affected. ADHD is three times more frequent in boys

than in girls. Around 30-50 % of people diagnosed during childhood show symptoms as adults and 2.5-5 % of the adults have the disorder (3).

The disorder was first clearly described by George Still in 1902. Others terms used for ADHD are minimal brain dysfunction or minimal brain damage (5).

ADHD is divided into three subtypes: a form with predominant attention deficit, one with predominant hyperactive-impulsive behavior and one combined (4).

MAIN ETIOLOGIC AND PATHOPHYSIOLOGIC FEATURES

Even if the cause of ADHD is not known, the disorder is believed to be the result of interactions between genetic and environmental factors (5). Twins studies demonstrated that the disorder is often inherited, genetics being involved in 75 % of the cases. Genetic factors seem to be also involved in the persistence of ADHD during adulthood. Genes involved are mainly regulating dopamine neurotransmission (DAT, DRD_4, DRD_5, $TAAR_1$, MAOA, COMT and DBH) (6,7).

From the evolutionary perspective, hyperactivity should have been beneficial in situation of risk exposure, like exploring new areas, thus should have been benefic for the community even if harmful for the individual (8).

A reduction in the volume of certain brain structures was observed in children with ADHD, as well as a proportionally important decrease in the volume of the left-sided prefrontal cortex. Posterior parietal cortex is also thinner in ADHD subjects (9).

Recent models of ADHD are demonstrating that the disease is associated with dysfunction in central neurotransmitter systems, especially those involving dopamine and norepinephrine. Dopamine and norepinephrine pathways which are projecting into the prefrontal cortex and striatum are responsible for the modulation of the executive functions (cognitive control of behavior), motivation, reward perception and motor function; these pathways play an important role in the pathophysiology of ADHD (10).

DIAGNOSIS

Diagnosis is established on person's childhood behavior and mental development, excluding effects of drugs, medications or psychiatric conditions, which otherwise may explain the symptoms. It may be regarded as the extreme of one or more common human traits. The diagnosis is not excluded or confirmed by response to specific medications. Imaging studies of the brain are not relevant for diagnostic purposes (11).

ADHD is classified among disruptive behavior disorders, along with oppositional defiant disorder, conduct disorder and antisocial personality disorder (12).

According to the American Psychiatric Association (DSM criteria) are differentiated three subtypes of ADHD: one subtype is mostly characterized by inattentiveness (easily distracted, forgetful, daydreamer, with concentration and completing tasks difficulties). The predominant hyperactive-impulsive type is manifesting as restless, hyperactive, with difficulties in waiting and remaining seated, immature conduct; the third type is a combination of the first two subtypes, or the combined type (13).

Inattention symptoms include: being easily distracted, missing details, switching frequently from one activity to another; difficulty in maintaining focused on one

task; not seeming to listen when spoken to; daydreaming, getting easily confused and moving slowly, showing difficulties in processing information as quickly and accurately as others; difficulty in focusing attention on organizing and completing a task or learning new data; becoming bored with a task after a few minutes (13).

Hyperactivity is characterized by fidget and squirm, talking continuously, trouble to sit during dinner, school or doing homework; the subject is all the time in motion and has difficulties in achieving quiet activities. These symptoms of hyperactivity tend to fade away with age and in teens and adults with ADHD they become an inner restlessness (14).

Impulsivity is revealed by symptoms such as: impatience, inappropriate comments, acting with no regard for consequences, difficulty in waiting (as their turns in games) and often interrupting others talking or activities.

Diagnosis is established in the presence of six to nine long term symptoms of inattention, hyperactivity-impulsivity or both, lasting for at least six months (15).

Symptoms should appear at the age of six to twelve, in more than one situation, like for example at home and at school, and they must cause social, educational or work related problems (14).

Differential diagnosis must take into consideration the bipolar disorder and borderline personality disorder. Symptoms of anxiety disorder, antisocial personality disorder and mental retardation may sometimes overlap with ADHD or may occur at the same time with ADHD. Diseases which symptoms may mimic ADHD are especially hyperthyroidism, seizure disorder, lead intoxication, sleep apnea and drug interactions (16). Primary sleep troubles may cause attention deficit, while ADHD may alter sleep quality; sleep problems must be treated in children with ADHD.

THERAPEUTIC OPTIONS

Management of ADHD is including behavioral therapies and medication, alone or in combination.

Behavioral therapies are recommended mainly in those cases with mild symptoms and in preschool aged. They include behavior therapy, cognitive behavioral therapy, interpersonal therapy, family therapy, school-based interventions, neuro-feedback (12).

An important factor in reducing psychological problems (such as major depression, school failure, criminality, drug use disorders) is the friendship with persons who are not involved in delinquent activities (17, 18).

Stimulant medications such as amphetamine are the therapy of choice being effective in approximately 80 % of cases.

Alternatives include bupropionum, guanfacine, clonidine, atomoxetine. Stimulant medication is also improving the academic performance (19).

Overdose of stimulants is associated with symptoms of mania; very rare (0.1 %) such symptoms may appear at therapeutic doses in the first weeks of treatment with amphetamine or methyl-phenidate. Use of stimulants in doses above the therapeutic range is associated with addiction and dependence (18,19).

PROGNOSIS

Proportion of children showing criteria for ADHD drop at half in the three years following the diagnosis, whether if treated or not. ADHD is persisting into adulthood in approximately 30-50 % of cases.

Generally, ADHD individuals are developing coping mechanism as they become mature, thus attempting to compensate their symptoms. However, higher risk for depression, anxiety and suicidal attempt is stressing the importance of surveillance and appropriate interventions in adults with ADHD (11, 16).

Controversies in what concerns ADHD are ranging from the opinion that ADHD should be viewed as situated in the normal range of behavior to viewing it as a genetic condition. Most specialists are considering it a medical condition, at least in the cases with severe symptoms (20).

CONCLUSIONS

In what concerns ADHD diagnosis, we notice that while the mild symptoms do not need to be diagnosed, most severe cases must be treated and followed-up since the disorder is interfering with social and educational activities, as well as with work in these subjects.

Recent data demonstrated that persistence of ADHD during adulthood (2.5-5 % of the adults) is increasing the risk for development of psychiatric conditions (depression, anxiety, suicidal behavior) which recommend the surveillance and adequate therapy in these cases.

NEWS

TIMING OF ESOPHAGECTOMY IN MULTIMODAL THERAPY OF ESOPHAGEAL CANCER

Neoadjuvant radiochemotherapy [n(R)CT] has become the standard of care in the multimodal therapy concept for patients with locally advanced esophageal cancer. The question is whether the length of the interval between completion of n(R)CT and surgery can affect the postoperative outcome, tumor response and long-term survival. In a study of 106 patients with adenocarcinoma and squamous cell carcinoma of the esophagus, treated between 2006 and 2013, on the basis of the median time interval to surgery, patients were divided into two groups [group A $\leq$ 40 days (n = 54) and group B> 40 days (n = 52)] and compared concerning demographic data, preoperative risk scores, morbidity, outcome, tumor response and long-term survival. Group A showed a trend towards a higher mortality risk as preoperatively assessed by the physiological and operative severity score for the enumeration of mortality and morbidity in esophagogastric surgery patients (O-POSSUM) (p = 0.064) and group B showed a trend towards a higher rate of complete responders (p = 0.097). So, concerning perioperative morbidity and mortality, delayed surgery after n(R)CT shows no benefit for the patient's outcome; however, the rate of complete tumor response is higher in patients with a time interval of more than 40 days, although this does not influence long-term survival or recurrence rates. (Müller A.–K. et al. Timing of esophagectomy in multimodal therapy of esophageal cancer : Impact of time interval between neoadjuvant therapy and surgery on outcome and response. *Der Chirurg* 09.2015, doi: 10.1007/s00104-014-2916-6. 86 : 9 : 874-880).

DEPRESSION - A FELLOW TRAVELER WITH SYSTEMIC LUPUS ERYTHEMATOSUS (Abstract): Systemic lupus erythematosus (SLE) is a chronic multisystem inflammatory disorder that occurs primarily in women of childbearing age, immunologic abnormalities being a prominent feature of the disease. Psychiatric disorders frequently coexist, depression being the most common mood disorder in neuropsychiatric lupus. This literature review was performed through searching MEDLINE database for full-text English-language articles - original research, systematic review and updates published in the last five years (2010-2015), using the keywords "depression and systemic lupus erythematosus". The main outcomes identified were prevalence and predictors of depression in various cultural and ethnic groups, depression-related clinical issues (suicidal ideation, cognitive impairment, altered body image, sleep and sexual disturbances, influence of SLE treatment), and influence on quality of life. A multidisciplinary approach that takes into account the polymorphism and individual variability of the SLE clinical manifestations helps to improve early detection of depression, which is responsible for the increased risk of comorbidities, suicidal attempts, decreased treatment adherence, and impaired quality of life. Physicians across all specialties involved in the care for lupus patients should be aware of the major prevalence of this condition, while helping patients to cope with their disabling disease. **Keywords**: DEPRESSION, SYSTEMIC LUPUS ERYTHEMATOSUS, NEUROPSYCHIATRIC LUPUS.

Systemic lupus erythematosus (SLE) is a chronic multisystem inflammatory disorder that occurs primarily in women of childbearing age, immunologic abnormalities being a prominent feature of the disease. Diagnosis is based on clinical and immunological criteria as defined by the 1997 American College of Rheumatology (ACR) and the 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria (1).

The course of the disease is chronic, relapsing, and unpredictable, with flares and remissions that may last for years. Medication used to treat SLE depends on the severity of the disease and clinical manifestations, including biologic and nonbiologic disease-modifying antirheumatic drugs (DMARDs),

corticosteroids and nonsteroidal anti-inflammatory drugs, and antimalarials (2).

In chronic somatic diseases, like SLE, psychiatric disorders frequently coexist, patients having increased level of worry and concern about their condition, the psychological disturbances negatively affecting their emotional status and quality of life and leading eventually to increased risk for disability and death (3, 4). Patients with lupus suffering from one or more neuropsychiatric symptoms, such as cognitive impairment, anxiety, depression, mood disorder, psychosis, represent a clinical category named "neuropsychiatric lupus" (NPL), which includes a broad spectrum of conditions, 12 central nervous system and 7 peripheral nervous system – related, according to the 1999 American College of Rheumatology recommendations (5). These can result in increased severity, refractoriness to medical treatment and marked functional impairment (6).

DEPRESSION AS PART OF THE NEUROPSYCHIATRIC LUPUS

Understanding of neuropsychiatric lupus is still limited, but several pathogenic pathways were identified, some of them related to depression (5, 7) (tab. I).

TABLE I

Pathogenic pathways in neuropsychiatric lupus (according to Kivity at al., 2015) (5)

Pathogenic pathway	Clinical relevance
Vasculopathy	small vessel thrombotic-vasculopathy in brains of NPL patients
Autoantibodies	➢ anti-ribosomal-P - lead to neuronal apoptosis ➢ anti-DNA/NR2 - neuronal apoptosis, hippocampal neuron damage coupled with memory loss ➢ anti-DNA 16-6 idiotype - correlate with disease activity, cause histological changes in the hippocampus and amygdale, affecting behavioral and cognitive functions in mice ➢ anti-phospholipid/anticardiolipin - activation of coagulation pathways, predisposing to focal neurological manifestations (stroke, transverse myelitis, chorea), seizures, migraine, and cognitive impairments ➢ anti-GABA - high levels in cerebrospinal fluid
Blood brain barrier disruption	enable auto-antibodies to penetrate the brain and cause their pathogenic effects, further inducing the production of pro-inflammatory cytokines (anti-ribosomal-P, anti-NR2 antibodies)
Cytokines	IL-2, IL-10, interferon (IFN)-α, IFN-γ elevated in serum and cerebrospinal fluid

Depression is the most common mood disorder in neuropsychiatric lupus, having a lifetime prevalence of up to 65% in SLE patients. An association of depression and specific antibodies directed at ribosomal-P, N-methyl-D-aspartate (NMDA) receptor, and other neuronal epitopes has been suggested (5, 8).

Symptoms of clinical depression in lupus are lack of energy, diminished sexual appetite, sleep disturbances, modified eating pattern, and fatigue (3, 9) that could be attributed to both conditions – SLE and depression. Sometimes clinical depression is a symptom of neuropsychiatric lupus, as a result of the complex interplay of biochemical abnormalities affecting the brain, but other times depression comes later in the course of disease, as a result of patient response to the burden of disease, social

consequences, and symptoms severity, leading to feelings of sadness, helplessness and rejection, both instances being part of a comprehensive approach to depression in SLE (10).

Physicians usually use the SLE Disease Activity Index (SLEDAI) to determine the level of disease activity and weather the flare is mild, moderate, or severe; but depression is not one of the specific symptoms on SLEDAI, needing other type of workup to determine it, and that might be a reason for overlooking this diagnosis and related-issues, even though they have a great impact on quality of life and the course of disease (11, 12). The importance of early identification of neuropsychiatric involvement in SLE, when symptoms could be mild, required the development and validation of simple clinical screening tools, such as physician-administered or self-reported standardized questionnaires. This assessment is challenging and there is need for validation in large cohort studies, cross-culturally adapted (6, 13).

This literature review was performed through searching MEDLINE database for full-text English-language articles - original research, systematic review and updates, published in the last five years (2010-2015), using the keywords "depression and systemic lupus erythematosus". The research initially identified 429 articles and excluded studies on topics involving cutaneous lupus erythematosus without systemic involvement, drug-induced lupus erythematosus, and pediatric age; a number of 30 articles were retained. The main outcomes related to depression in SLE patients were prevalence and predictors of depression in various cultural and ethnic groups, clinical issues depression-related (suicidal ideation, cognitive impairment, altered body image, sleep and sexual disturbances, influence of SLE treatment), influence on quality of life.

DEPRESSION IN LUPUS – PREVALENCE DATA AND PREDICTORS AROUND THE WORLD

There are many studies conducted all over the world to help identifying the symptoms and particular appearance of depression related to local culture and religious beliefs. In some geographical areas, depression may be underrated and patients do not receive the proper treatment.

In a recent study on European population, the prevalence of depression in SLE subjects is 16.6% compared to 6.7% in the general population ($P < 0.001$), as resulted from the ODIN study (Outcome in Depression International Network) and it is not related to disease activity or organ damage (14).

In Asia, a Chinese cross-sectional study (15) investigated the relationship between disease parameters, quality of life, and psychological status in patients with SLE. It included 170 patients with SLE and 210 healthy individuals matched for age, gender, education, and work status. This study revealed that 20.3% of SLE patients were diagnosed with anxiety and 32.9% with depression, significantly higher than healthy people. Severe disease status, higher disease activity and lower quality of life significantly correlated with depression and anxiety in the Chinese SLE patients. Risk factors included poorer coping styles, ongoing life events, exposure to stress, and low social support. Impaired mental health and pain were the most powerful predictors of anxiety and depression in this study. A cross-sectional study conducted in Thailand on 62 SLE patients identified the presence

of depression in 45.2% and anxiety in 37.1% of the patients. It also concluded that higher anxiety score (HAM-A score) and younger age were significant predictors of depression in SLE (16). In addition, a retrospective study in Saudi Arabia found 15.2% SLE patients with depression and 17.4% with signs of psychosis (17).

In South America, a Chilean study examined 83 patients with SLE for common mental disorders, psychological sufferance, disease activity (SLEDAI), and biological determinants. A major depressive episode was the most frequent diagnosis (21.7%), suicidal ideation was present in 9.6%, but there was no association with disease activity and anti-ribosomal P antibodies (18).

A major longitudinal study enrolling 1609 North-American SLE patients in the Hopkins Lupus Cohort aimed at identifying the predictors of depression in lupus. The trial demonstrated an incidence of depression of 29.7 episodes per 1000 person-years and found several independent predictors of depression in lupus: recent diagnosis, non-Asian ethnicity, myelitis, cutaneous activity, disability, and higher-dose prednisone (>20 mg daily) (19). In another cross-sectional study that used structured clinical interview techniques for diagnosing depression, major depressive disorder was the most prevalent disorder (17%), followed by minor depression (6%) and dysthymia (4%) (20).

DEPRESSION-RELATED CLINICAL ISSUES

Sleep and sexual disturbances. Sleep (insomnia, hypersomnia) and sexual disturbances are common in patients coping with chronic disease, lupus included. An Italian clinical trial compared 81 female SLE patients with 53 hypertensive female patients as controls regarding the sleep pattern. The collected data showed a 2.5 times higher probability of poor sleep quality in SLE patients compared to the hypertensive ones. Depressive symptoms were significantly associated with sleep disturbances in SLE, but not with the activity or duration of the disease (21). These findings suggest that depression might be responsible for poor sleep quality in SLE.

Sexual function in women with SLE was analyzed in a cross-sectional, case-control study including 65 lupus patients and 55 healthy subjects. Women with SLE reported significantly impaired sexual function, associated with somatization, obsessive-compulsive behavior, depression and paranoid ideation; multivariate analysis indicated that depression, vitality and Positive Score Discomfort Index (PSDI) were significantly associated with low sexual function, eventually affecting the quality of life (22).

Suicidal ideation. It is of major importance to evaluate the patients diagnosed with depression and SLE for suicidal ideation, in order to prevent fatal events. A study conducted in Iran (23), which included 85 SLE patients, concluded that 60% of the patients had depression, the most common depressive symptoms being fatigue (88%), irritability (82%), sadness (77%), and somatic preoccupation (76%). The least common symptoms of depression were weight loss (34%), low energy level (28%), and suicidal ideation (10%). In a larger Chinese study, including 285 patients, 34% had current suicidal ideation. The individual risk factors found by the researchers were religious beliefs, financial problems, duration of SLE, poor family functioning, and negative coping style (24).

Cognitive impairment associated to depression. Patients presenting with de-

pression and SLE have to be screened for cognitive impairment because they seem to be more exposed (9) and it may have a deleterious influence on the evolution of the disease and course of treatment. In addition, it seems that SLE patients with cognitive dysfunction have higher titers of auto-antibodies also linked to depression, such as anti-ribosomal-P, anti-N-methyl-D-aspartate (NMDA) glutamate receptor (5, 8). It is known that cognitive impairment is present in 80% of SLE patients ten years after diagnosis, but it could exists even in early stages, related to depression. A multicenter cohort study included 111 patients newly diagnosed with SLE who underwent depression and cognitive function testing, the results showing that depressed lupus patients had poorer cognitive performance. Treatment for depression might improve cognitive functioning in these patients, but further studies are needed (25).

Body image. Body image is also affected in chronic disabling disease with significant cutaneous and musculoskeletal involvement like lupus. Studies showed that body image quality of life inventory (BIQLI) scores were significantly worse in SLE patients than in non-SLE patients, being correlated with self-reported depression and overall damage (26). Education, cognitive behavioral therapy, and cosmetic training lead to improved measures of body image, psychological well-being, and quality of life, showing that altered body image is modifiable in SLE (27).

Associated clinical conditions in SLE patients with depression. From the clinical picture of SLE, lupus arthritis seems to be related to depression. A cohort study of 127 lupus patients identified moderate or severe depressive symptoms in 41.7% of patients, the most significant variable associated with these symptoms being pain from lupus arthritis (28). A Spanish study including 84 SLE patients aimed to determine the possible relationship between fibromyalgia and psychiatric disorders in SLE. First of all, it identified fibromyalgia in 35.7% of the SLE patients, depressive symptoms in 19% and anxiety in 35.7%. The authors concluded that there is a high prevalence of fibromyalgia in SLE patients and a strong association with depressive and anxiety symptoms ($P<0.001$), but little or no impact of disease activity on psychiatric symptoms (29).

Influence of immune response. In this respect, there are conflicting results: some trials revealed that cerebro-reactive autoantibodies present in the cerebrospinal fluid (anti-N-methyl-D-aspartate and anti-ribosomal P) can cause significant damage to brain neurons (including the amygdala), potentially leading to depressive symptoms (5, 8) while others did not demonstrate a significant association between anti-ribosomal P antibodies and depression in SLE (18). The potential role of pro-inflammatory cytokines in developing depression and poorer quality of life is still unclear. A case-control study conducted in Singapore revealed that higher serum tumor necrosis factor-alpha levels are significantly associated with more severe depressive symptoms and decreased quality of life as assessed by SF-36, in patients with SLE (30).

Influence of SLE treatment. Medication is critically important in the therapeutic approach of SLE but many drugs have side effects that include depression. Glucocorticoids are widely used but they display severe side effects after prolonged use, such as hypertension, dyslipidemia, diabetes, behavioral changes, immunosuppression, memory impairment, mood disturb-

ances, gastrointestinal bleeding, glaucoma and cataract, osteoporosis.

It is necessary to strictly asses the patients prior to prescribing this drug, especially in larger doses (> 20 mg daily), in order to maintain the lowest necessary dose to achieve therapeutic effects, even though it is not clearly defined that corticosteroids are exclusively responsible for the appearance of major depressive disorder in patients with SLE. One study on 57 female patients with SLE found that of these up to 80% were treated with at least one corticosteroid and a large number of them presented emotional disturbances, such as depressive state, that coincided with the prolonged use (31) while another prospective longitudinal study (32) highlighted the importance of psychiatric examination prior to prescribing corticosteroid therapy because of the early onset of depression and anxiety during the first week of treatment. Risk factors were higher doses and prior history of psychiatric disorders, underlying the need to identify patients at risk, because up to 22% of the patients with depression and corticosteroid treatment develop a severe form of disease, with suicide attempts (33). So far, there is no particular medication that had been shown specific for treating depression associated with SLE.

Quality of life in patients with SLE and depression. Systemic lupus erythematosus is a long-term complex disorder also affecting social functioning. When assessing patients with SLE it is important to take into account the influence of depression on patients' quality of life. In patients in the PATROL study (Patients Reported Outcomes in Lupus), namely 125 Caucasian and Hispanic lupus patients, quality of life assessment was done using the Short Form-36 (SF-36) questionnaire. Depression, and not disease activity as measured by SLEDAI, significantly correlated ($p<0.0001$) with the majority of SF-36 domains, and appeared to have a major impact on quality of life in both ethnic groups with SLE (33).

Major contributors to decreased quality of life in lupus include fatigue, fibromyalgia, depression, cognitive dysfunction, altered body image, sleep and sexual dysfunction, but these are not related to disease activity (22, 26, 34). A meta-analysis including six randomized controlled trials comprising 394 participants and conducted by Chinese researchers concluded that psychological interventions (cognitive-behavioral therapy) significantly reduced the degree of depression (standard mean difference = −0.44, 95% [CI]: −0.78–0.10; P = 0.01), improving the quality of life, even if there was no effect on pain, disease activity, fatigue or mental health (4).

In the absence of large epidemiological studies and SLE databases there are multiple areas of "unmet need" in these patients, including firstly delayed diagnosis, depression/anxiety symptoms, sleep disturbances, and poorer quality of life, as a recent Australian systematic review has shown (35).

CONCLUSIONS

Given the polymorphism and individual variability of the SLE clinical manifestations we believe that the multidisciplinary approach could help improve early detection of depression, which is responsible for the increased risk of comorbidities, suicidal attempts, decreased treatment adherence, and impaired quality of life. Based on the available research data, physicians across all specialties involved in caring lupus patients should be aware of the major prevalence of

this condition, while helping patients to cope with their disabling disease.

Patients with systemic lupus erythematosus should be permanently encouraged, right from the time of diagnosis, to build-up a personal strategy of defense against depression, through physical activity, psychological counseling, cognitive behavioral therapy, and social exercise, in addition to the pharmacological approach when needed.

ORTHOREXIA NERVOSA: THE UNHEALTHY OBSESSION FOR HEALTHY FOOD (Abstract): The aim of this paper is to inform about a form of food extremism which has been named orthorexia (right feeding). Although orthorexia nervosa has the clinical criteria for being structured as a unique, distinctive disease, with physical, psychological and social consequences, it is not yet present in the recent psychiatric classifications. There are still controversies whether it can be included in the eating or in the obsessive-compulsive disorders. Orthorexia represents a pathological obsession for healthy eating characterized by qualitative food restrictions, strict avoidance of foods considered "impure" and ritualized ways of eating. Orthorectics create a world of their own in which they are in control of the safety and purity of the foods they eat, searching for spirituality in the kitchen and feeling superior due to their choices, even if the results are the deterioration of health and social isolation. There is still need for population studies, based on valid and unanimously recognized criteria, in order to have the complete picture of this new pathology that has both medical and social origin. **Key words:** ORTHOREXIA, ORTHOREXIA NERVOSA, EATING DISORDERS.

The 21st century can be called the century of consumption. Food, especially low nutritional value food, is available at reasonable prices. The abundance of foods and technologies to produce food, the accumulation of precise data about the physiological effects of foods, and discussion over the mono-cultural traditional food practices, all lead to a crisis in food model. The result is an eating behavior characterized by anxiety and ambiguity that evolves on one hand to the glorification of traditional foods that carry symbols and on the other hand to a modern diet founded on an individual genetics invalidated by studies, but extrapolated to everybody (1).

Obesity is the calamity of the century. The prevalence of obesity is rising rapidly with fatal consequences for health, through suffering and costs. In the same time, we face the expectations of being healthy and normal weight in order to conform to the ideals of the society. The epidemic of obesity has led to a cultural change that stresses the importance of healthy behaviors in order to achieve the desired weight. Many persons are tempted to change their lifestyle, by adhering to different diets, exercising and managing stress (2). One might argue that this change that focuses on a healthy lifestyle is a positive result of the obesity epidemics. Through a variety of sources, the population becomes exposed to a series of information about ways to im-

prove their diet. It becomes obvious that different types of food products are associated by some persons with health (3). The inflation of legislation to regalement and manage dietary risks generates a perverted effect, increasing the imaginary dangers. The rational of the consumer is generally binary (with risk or without risk) and non-probabilistic. The psychological impact of legislation of risk is stronger than the risk itself and brings a bonus of power to self-control in order to obtain the desired hygiene or at least the illusion of food security. However, in recent years, evidence has emerged suggesting that a subset of the population takes healthy eating too far, towards food "extremism", with negative physical, psychological and social consequences (4). These are the orthorectics.

The definition of orthorexia. The term orthorexia means rightful eating, being a combination of the Greek words "orthos" = right, correct and "orexis" = appetite.

Orthorexia is not a weight loss diet, but a pathological fixation for food perfection. Orthorectics are not just obsessed with rightful eating, but have also a specific attitude regarding food, the cooking of food and avoidance of certain foods that they consider bad for their health. The quality of the products they consume is more important than personal values, carrier related plans or social relationships. The desire to eat healthy foods is not an abnormal behavior in itself, but it is defined as orthorexia nervosa (ON) only when it makes the person give up their normal lifestyle. ON can be seen as a negative behaviour when optimal nutrition is related to anxiety and concern regarding health and the quality of foods. Orthorectics install a series of constrains which affect the nature, the terms and the rhythm of nutrition (5).

Initially conceptualized by Bratman in 1997 (6), the term ON was invented to describe an "unhealthy fixation to eat healthy foods" (7). Although Bratman claims that ON is an unique type of eating disorder, in which factors like taste or pleasure are less important, and health and nutritional value are more important and which focuses on the quality of foods, rather than the quantity, other researchers indicate that this uniqueness cannot be demonstrated (8,9).

It is not fully investigated how dangerous the clinical disorders of ON are to the individual, but, based on personal experience, Bratman claims that ON is a disorder with negative physical, psychological and social effects which escalade with time, in an orthorectic society (10).

The physical consequences attributed/associated with ON. The negative physical consequences of ON result from the fact that strict diets exclude groups of important foods. ON frequently leads to avoidance of previously preferred foods, thus reducing the number of foods consumed. People with ON exclude from their diets everything that is considered "impure" or imperfect in any way. This eating style has serious consequences through caloric deficit and lack of vitamins and minerals (11). Ironically, the quest for dietary perfection can lead to anemia, osteopenia and other medical consequences (12). In the desire to add years to life, orthorectics make life meaningless. This focus becomes an obsession, self-discipline becomes self-punishment and the effort could turn into addiction.

The psychological consequences attributed/associated with ON. People with ON can dedicate a long time to planning, organizing, buying and preparing unpollut-

ed and healthy food. They can feel the need to "punish" themselves with more and more drastic food restrictions when they disobey the self-imposed rules. Some people may feel that adhering to a perfect diet help them reach a feeling of personal purity and perfection. After a while, the strict control over food leads to a feeling of relief, energy and power. Control over personal eating habits is viewed as rewarding, which only strengthen their beliefs (13). One can detect some pseudo-spiritual connotations with eating pure foods, religious elements and specific rituals in the kitchen, regarding cooking (12). People with ON describe their symptoms as an overwhelming, obsessive physical and psychological desire to feel pure, natural and healthy, which begins to overcome other pleasant aspects of life (4). "Healthy" eating becomes an (unhealthy) addiction and "pure" eating is the only way to be healthy, even if the cost is losing other opportunities of life and just the illusion of total safety and the desire for complete control.

The social consequences attributed/ associated with ON. People who suffer from ON are often socially isolated, as a consequence of their lifestyle, avoiding groups where their food choices could be questioned or contested. They may feel the need to bring to dinners their own food, which fulfill their idealized nutritional standard and for which they spent their whole time searching and preparing. These persons are characterized by discipline and a sense of moral superiority, of extreme pride over those who eat incorrectly, which only increases their social isolation from all those who do not understand the fact that food could be ritualized (4,6). People who think that only their diets are acceptable go to extreme length to convince those around them who do not adhere to this new „religion" or who do not show devotion to healthy food.

Through these three types of consequences (physical, psychological and social), Bratman suggests that ON is a distinctive psychiatric disorder. As research progressed, the possibility was raised that ON is a version of an eating disorder or an anxiety disorder (9).

ON as an eating disorder. Eating disorders are psychiatric disorders defined as abnormal eating habits which could include either insufficient or excessive food intake, detrimental to the physical and mental health of an individual. Anorexia nervosa (AN) and Bulimia nervosa (BN) are the most common specific forms of eating disorders, but included in the classification are also Binge Eating Disorder (BED) and Eating Disorder Not Otherwise Specified (EDNOS).

Bratman himself shows some resembles to AN. Like anorectics, people with ON are so focused on control over food that their life unbalances by losing contact with previous food habits and the perspective of having to change the new eating behavior. ON and AN are considered to have in common a genetic predisposition for perfection, high levels of anxiety and a need to control the environment (14). Orthorectics often prefer to starve than to eat foods they consider "impure".

However, one should notice that, despite the shallow characteristics which could indicate some overlap, diagnosis of AN implies other supplemental important criteria, like reduced weight, compensatory behaviors and amenorrhea. As a result, some researchers (13, 15) suggested that, rather than being classified as an Eating Disorder, ON could be better considered a

risk factor for future eating disorders.

However, Bratman has observed two main differences between ON and eating disorders. First of all, in diseases like AN or BN, the disorders in eating are expressed quantitatively, whereas in ON, they are expressed qualitatively. More recent research indicate that this is not always true, as some persons with eating disorders have individualized rules about the quality of the foods they consume (8, 11). Bratman has claimed another difference between ON and eating disorders, which focuses on motivation. More precisely, he claimed that, unlike AN, where the goal is weight loss, people with ON are lead by the desire to obtain a feeling of perfection and personal purity (6). However, recent studies suggest that these motivations, especially those to reach perfection, are also present in people with AN (14, 16).

To the original arguments of Bratman, results of recent studies show that there are differences regarding the prevalence of ON in men and women. Both AN and BN are more frequent in women (17), but authors raise the possibility that ON is more frequent in men (7, 18, 19). However, one must notice that research about BED show the same results as for ON regarding the higher frequency in men (20).

ON as an anxiety disorder. Other arguments claim that ON could be better conceptualised as an anxiety disorder, especially as a variance of obsessive-compulsive disorder (OCD).

An obsession is an irrational thought which appears repeatedly. A compulsion is a certain behavior that a person does repeatedly with the aim of protecting themselves against an obsession. Obsessive-compulsive neurosis is one type of anxiety disorder in which patients realize that their obsessions are irrational but worry that they can become reality and face them by completing ritualized actions (compulsions). Ritualized behavior can reduce anxiety, distress of a person, but by no means can it bring any satisfaction or pleasure. Reducing risk through control increases fear of risk.

Bratman (6) describes as characteristics of ON the obsessive adherence to a strict diet, careful selection and examination of all foods in regards to their content, origin, presence of artificial ingredients/additives, preservatives, and others, detailing and engagement in extremely careful planning of meals, confrontation with guilt if there is deviation from self-imposed food restrictions. The ways of preparing food, the tools used in the kitchen and other instruments used are part of the obsessive ritual. The overlapping point between ON and OCD are anxiety and perfectionism. From this perspective, personal food restrictions in ON are meant to reduce anxiety related to food, which is determined by the current cultural focus on establishing models for healthy living (21). Obviously, in this moment, there is need for further studies in order to determine if ON is truly a distinctive disorder or it is better characterised as an OCD. In short, the exact nature of ON is unclear. It could also be argued that ON is not a psychological disturbance, but a tendency in society. Unfortunately, too many physicians recommend dietary restrictions for all sorts of diseases (asthma, allergies, irritable bowel disease) in order to eliminate certain “irritants” from the dietary plan. This could be a potential step towards developing food fixations (22).

The diagnosis of ON. Steve Bratman has proposed a test which includes 12 questions to detect orthorectics. In his opinion,

which is not generated by an empirical research, the diagnosis of ON would be put when a person: spends more than 3 hours per day thinking about and preparing healthy food**;** feels superior to those with differing eating habits**;** follows a particular self imposed dietary regimen rigidly and engages in compensatory restriction to make up for any dietary indiscretions**;** attaches self-esteem to adherence to the self imposed diet (feeling of self-satisfaction when complying with the self imposed dietary regimen)**;** makes consumption of healthy diet the central focus of life, at the expense of other personal values, relationships, previously enjoyed activities, and sometimes, ironically, physical health**;** makes nutritional value of meal more important than the pleasure of eating it.

Domini et al (23) have validated a questionnaire for the diagnosis of ON. It is known as the ORTO-15 questionnaire and has 15 multiple choice questions (with answer choices: always, often, sometimes, never) which evaluate the prevalence of ON. A score of 1 is given to the answer that indicates orthorexia, where as a score of 4 is given to the answer indicating "health". The sum of the scores represents the final score. Donnini et al proposed a cut-off score of 40 for ORTO-15 test. A score below 40 indicates that the person has orthorexic tendency. In this way, the Italian researchers reported a prevalence of ON of 57.6%. If the cut-off value was set at 35, the prevalence droped to 21% (24). In 2015, the questionnaire was validated also for adolescents (25).

The application of the procedure developed by Robins and Guze in 1970 (26) to the diagnosis framing of ON in comparison to other eating or anxiety disorders shows the gaps in research. The few existing studies focus entirely on the first step of determining diagnosis validation (clinical description), whereas the diagnosis construction of ON has to demonstrate other four criteria: Laboratory findings; Delimitation from other disorders; Follow-up studies; Family studies.

The majorities of studies focus on very small study samples like homogeneous groups of medical students, nutrition and dietetics students or performance artists, and lack experimental rigors. There is a lack of systematic investigation and thus the studies are not comparable. In 2013, Varga et al found in literature only 11 studies regarding ON (27). Even in this small number of studies, the applied criteria and the results regarding the prevalence of ON were extremely variable. The average prevalence of orthorexia was 6.9% for the general population and 35-57.8% for high risk groups (health professionals, artists). Risk factors include obsessive-compulsive characteristics, previous food related disorders and socio-economic status (18, 19, 21, 28-32).

Current practices suggest that, in order to have success in treating ON, one should combine psycho-education, cognitive behavior therapy and sometimes medication (5, 12, 22).

CONCLUSIONS

The validated diagnosis criteria for ON are somehow controversy (33,34), because ON has not been officially recognized as a distinctive disorder by the American Psychiatric Association in Diagnostic and Statistical Manual 5th edition (DSM-5), or by the World Health Organization's International Classification of Diseases (ICD-11). There is need for the development of supplementary psychometric tests in order to be sure that future research will be im-

proved by using reliable and validated evaluation instruments. Establishing prevalence rate, determining psycho-social risk factors and psycho-pathological co morbidities will create efficient therapeutic interventions (35).

VITAMIN D DEFICIENCY AND THE CLINICAL CONSEQUENCES (Abstract): Vitamin D is important for good health, growth and strong bones. Vitamin D is mostly made in the skin by exposure to sunlight. Most foods contain very little vitamin D naturally, though some are fortified with added vitamin D. Hypovitaminosis D is associated with cardiovascular disease, the metabolic syndrome, type 2 diabetes mellitus, cancer as well as with increased mortality. Further, Vitamin D deficiency is related to depression and impaired cognitive function. Increasing age and elevated body fat mass contribute to an increased risk of Vitamin D deficiency. A mild lack of vitamin D may not cause symptoms but can cause tiredness and general aches and pains. A more severe lack can cause serious problems such as rickets (in children) and osteomalacia in adults). During menopause, the decline of estrogens results in increased bone turnover, a decrease in bone mineral density and elevated fracture risk. Treatment is with vitamin D supplements. Some people are more at risk of vitamin D deficiency, and so are recommended to take vitamin D supplements routinely. These include all pregnant and breastfeeding women, all infants (babies) and young children aged 6 months to 5 years, people aged 65 and over, and people who are not exposed to much sun. There are precise recommendations regarding a sufficient Vitamin D intake in order to prevent bone loss in peri- and postmenopausal women. It is also recommend routine supplements for certain people with darker skin, and for people with certain gut, liver or kidney diseases. **Keywords:** VITAMIN D DEFICIENCY, RICKETS, OSTEMALACIA, VITAMIN D SUPPLEMENTATION.

Vitamin D has been well-known for its function in maintaining calcium and phosphorus homeostasis and promoting bone mineralization. In the past few years, there has been a proliferation of publications on the effects of vitamin D and/or calcium on skeletal and nonskeletal health. In 2011 at Annual Meeting and Clinical Congress of the American Association of Clinical Endocrinologists Professor Paul D. Miller(1) presented a manuscript which represents a systematic review of data from the search engines of PubMed, Medscape, and Scopus. The search words used were "vitamin D", "calcium", "cardiovascular events", "cardiovascular mortality", "all-cause mortality", "vascular calcification", "chronic kidney disease", "renal stones", and "hyper-calciuria". This presentation have followed of many other that they have tried to give an answer to what extent the level of vitamin D is responsible for bone patholo-

gy as well as and other chronic disease. Another question has been which is optimum level of vitamin D to prevent these diseases. Most of the evidence is derived from case-control and cohort population studies. Minimal data are derived from prospective, double-blind, placebo-controlled studies. The evidence is, therefore, limited by the nature of the study designs.

VITAMIN D. METABOLISM AND BIOLOGICAL FUNCTIONS

Humans obtain vitamin D through dietary intake and exposure to sunlight. In this regard, even with the most intense and prolonged sunlight exposure, the maximum level of vitamin D that can be achieved is approximately 60 ng/mL. Cutaneous vitamin D3 production is influenced by skin pigmentation, sunscreen use, time of day, season, latitude, altitude, and air pollution(2) .Very few foods naturally contain vitamin D.

The two major biologically inert precursors of vitamin D are vitamin D3 (cholecalciferol) and vitamin D2 (ergocalciferol) . Vitamin D3 is formed when 7-dehydrocholesterol in the skin is exposed to solar ultraviolet B, and then converted to previtamin D3. Excess UVB rays transform previtamin D3 into biologically inactive metabolites, tachysterol and lumisterol. Vitamin D2 is plant derived, produced exogenously by irradiation of ergosterol, and enters the circulation through diet. Both vitamin D precursors resulting from exposure to the sunshine and the diet are converted to 25-hydroxyvitamin D [25(OH)D] (calcidiol) when they enter the liver. 25(OH)D is the major circulating form of vitamin D. In order to be biologically active, additional hydroxylation in the kidneys is needed to form active 1,25-dihydroxyvitamin D [1,25(OH)2D] (calcitriol)=Hormone D(3). The 1,25(OH)2D performs many of its biologic functions by regulating gene transcription through a nuclear high-affinity vitamin D receptor (VDR)(4).This active metabolite of vitamin D binds to the nuclear VDR, which binds retinoic acid X receptor to form a heterodimeric complex that binds to specific nucleotide sequences in the DNA known as vitamin D response elements. There are estimated to be 200 to 2000 genes that have vitamin D response elements or that are influenced indirectly, possibly by epigenetics, to control a multitude of genes across the genome(4).It is universally accepted that the circulating level of 25-hydroxyvitamin D should be used as an indicator of vitamin D status due to its ease of measurement, long half-life in circulation (approximately 2 or 3 weeks), and the correlation of its level with clinical disease states . Vitamin D plays an important role in maintaining an adequate level of serum calcium and phosphorus. Without vitamin D, only 10 to 15% of dietary calcium and about 60% of phosphorus is absorbed (5). Therefore vitamin D has a great effect in forming and maintaining strong bones. It has also recently been found that vitamin D receptors exist in a variety of cells thus it has a biological effect on more than mineral metabolism (6). The 1,25(OH)2D interacts with its VDR in the small intestine to increase the efficiency of intestinal calcium absorption from approximately 10% to 15% up to 30% to 40% and intestinal phosphorus absorption from approximately 60% to 80%(7). It also interacts with VDR in osteoblasts to stimulate a receptor activator of nuclear factor kB ligand, which, in turn, interacts with receptor activator of nuclear

factor kB on immature preosteoclasts, stimulating them to become mature bone-resorbing osteoclasts (8). The mature osteoclast removes calcium and phosphorus from the bone to maintain blood calcium and phosphorus levels. In the kidneys, 1,25(OH)2D stimulates calcium reabsorption from the glomerular filtrate(7). The VDR is present in most tissues and cells in the body. Many of these organs and cells, including the brain, vascular smooth muscle, prostate, breast, and macrophages, not only have a VDR but also have the capacity to produce 1,25(OH)2D(7). This production probably depends on the availability of circulating 25(OH)D, indicating the biological importance of sufficient blood levels of this vitamin D metabolite(8).

VITAMIN D DEFICIENCY

Vitamin D deficiency has been recognized as a pandemic phenomenon with a variety of health consequences (2). Low vitamin D status has been associated with an increased risk of type 1 diabetes mellitus, cardiovascular disease, certain cancers, cognitive decline, depression, pregnancy complications, autoimmunity and allergy (3).

The US Endocrine Society recommended that vitamin D deficiency be defined as a 25(OH)D level of 20 ng/mL or less, vitamin D insufficiency as 21 to 29 ng/mL, and vitamin D sufficiency as 30 ng/mL or greater for children and adults. It suggested that maintenance of a 25(OH)D level of 40 to 60 ng/mL is ideal, and that up to 100 ng/mL is safe (9). Recent recommendations of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO)(10) for the optimal management of elderly and postmenopausal women regarding vitamin D supplementation have also indicated that patients with serum 25(OH)D levels less than 20 ng/mL have increased bone turnover, bone loss, and, possibly, mineralization defects compared with patients with serum 25(OH)D levels of 20 ng/mL or greater. Similar relationships have been reported for fragilty, nonvertebral and hip fracture, and all-cause mortality, with poorer outcomes at less than 20 ng/mL. Thus, ESCEO recommended that 20 ng/mL be the minimal serum 25(OH)D concentration at the population level and in patients with osteoporosis to ensure optimal bone health. Also, in fragile elderly individuals who are at elevated risk for falls and fractures, ESCEO recommended a minimal serum 25(OH)D level of 30 ng/mL for the greatest effect on fracture(10).

CAUSES OF VITAMIN D DEFICIENCY

There are many causes of vitamin D deficiency. Generally, they can be divided into two groups: UVB-related deficiency and medical/physical condition-related deficiency.

UVB-related deficiency. *The elderly*, due to the decreased presence of skin 7-dehydrocholesterol which is the precursor for UVB mediated synthesis of vitamin D, are particularly at risk of vitamin D deficiency. Moreover, reduced mobility or institutionalization that discourages sun exposure, reduced renal production of 1,25-dihydroxyvitamin D as well as decreased intake of fortified foods pose great difficulties in vitamin D formation in body. People with *dark skin* have great amounts of melanin in their epidermis. Melanin competes with 7-dehydrocholesterol for absorption of UVB photons. Therefore, people of color are less efficient in producing vitamin D than are whites. It has been established that

the ozone layer can absorb UVB. Zenith angle decides the thickness of ozone layer which sunlight needs to penetrate and it is dependent on factors such as *time of day, season of the year, and latitude.* Thus those factors have great effects on vitamin D production (11). *Sunscreens can* efficiently absorb UVB radiation. This dramatically prevents the interaction of UVB with 7-dehydrocholesterol, the process of previtamin D3 generation.

Medical / physical condition - related deficiency. As a fat-soluble vitamin, vitamin D requires the presence of dietary fat in the gut for absorption. Certain pathological conditions, such as Crohn's disease, cystic fibrosis , celiac disease, surgical removal of part of the stomach or intestines are associated with *fat malabsorption* and thus may lead to vitamin D deficiency. It is well recognized that long-term use of some *antiepileptic drugs*, including phenobarbital, phenytoin, and carbamazepine and the antimicrobial agent rifampicin (RIF) can result in osteomalacia. *Chronic kidney disease* such as patients with stage 4 or 5 chronic kidney disease, as well as those requiring dialysis, leads to an inability to make sufficient 1,25-dihydroxyvitamin D which has a direct effect in inhibiting parathyroid hormones expression. *Obese people* are prone to be vitamin D deficient since they have lower 25 hydroxyvitamin D levels . A number of studies proved that the vitamin D3 precursor 7-dehydrocholesterol levels in the skin of obese people were not significantly different from non-obese people. One explanation was that the subcutaneous fat, which is known to store vitamin D, sequestered more of the cutaneous synthesized vitamin D, which results in less release of vitamin D from the skin into the circulation in the obese subject than non-obese subject (12).

VITAMIN D INADEQUACY- EPIDEMIOLOGY

Prevalence of vitamin D deficiency in adolescents and adults. It has been estimated that 20% to 80% of US, Canadian, and European men and women are vitamin D deficient. The prevalence of serum 25(OH)D levels less than 20 ng/mL was almost one-third of the US population (32%). In the Healthy Lifestyle in Europe by Nutrition in Adolescence study, 25(OH)D levels less than 30 ng/mL were reported to be approximately 80% in adolescents from the 9 European countries. In a study on the vitamin D status of Australian adults, vitamin D deficiency (25[OH]D <20 ng/mL) was 31% (22% in men and 39% in women); 73% had 25(OH)D levels less than 30 ng/mL(13,14).

Vitamin D status during pregnancy, birth and childhood. Maternal vitamin D deficiency predisposes to low vitamin D stores in the newborn and increases infantile rickets because the mother is the only source of vitamin D during pregnancy. The prevalence of vitamin D deficiency and insufficiency during pregnancy is of special concern and ranges from 8% to 100%, depending on the country of residence and the definitions of vitamin D deficiency and insufficiency. In the United States, vitamin D deficiency and insufficiency is estimated to be 27% to 91% in pregnant women. This rate is estimated to be 36% to 65% in Canada, 45% to 98% in Asia, 70% to 100% in Europe, and 25% to 65% in Australia and New Zealand. In the United States, it is estimated that 50% of children aged 1 to 5 years and 70% of children aged 6 to 11 years are vitamin D deficient or insufficient (12,13).

VITAMIN D INTAKE IN DIFFERENT CONDITIONS

Musculoskeletal consequences of vitamin D deficiency. The skeletal consequences of 25(OH)D insufficiency include *secondary hyperparathyroidism*, increased bone turnover and bone loss, a decrease in BMD due to the increased bone resorption by PTH as well as a mineralization defect causing *osteomalacia*, and increased risk of low trauma fractures(13). The most common etiology of *rickets*, historically and presently, is vitamin D deficiency. Children begin to manifest classic clinical signs of rickets between 6 months and 1.5 years that include rachitic rosary, widened epiphyseal plates at the end of long bones, and bowing deformities of the legs. Proximal muscle weakness is a prominent clinical feature of vitamin D deficiency (13).

Osteoporosis. Approximately 33% of women aged between 60 to 70 and 66% of those over 80 have osteoporosis . Vitamin D deficiency is associated with the marked suppression in intestinal Ca absorption and the impairment of Ca balance, which results in low bone mineral content and density. Reduced bone mineral density (BMD) increases the risk of fractures, which significantly contributes to morbidity and mortality of older persons (15). Most evidence suggests that adequate calcium and vitamin D intake along with exercise during childhood will maximize bone mineral content that can be sustained in young and middle aged adults as long as they also have a healthy lifestyle, adequate calcium intake, and a healthy vitamin D status. Accruing maximum bone mineral content during childhood, and maintaining peak bone mineral density in young and middle-aged adults, will likely reduce the risk of fracture later in life, when there is a disruption in bone remodeling due to menopause and aging.

Nonskeletal consequences of vitamin D deficiency. A large number of trials have been conducted over the past two decades into the effects of vitamin D on disease management and prevention. Observational studies have found a decreased risk of many disorders, including certain types of cancer, mental disorders, infectious disease, cardiovascular disease, type 2 diabetes mellitus, and autoimmune disorders, associated with serum 25(OH)D levels greater than 28 to 32 ng/mL(7). It has, therefore, been argued that 25(OH)D levels should be in the range of 28 to 40 ng/mL to maximize these nonskeletal benefits (13).

Autoimmune diseases. Vitamin D has been defined as a natural immune modulator. Epidemiologic, genetic, and basic science studies indicate a potential role of vitamin in the pathogenesis of certain systemic and organ specific autoimmune diseases, such as type 1 diabetes mellitus, multiple sclerosis, rheumatoid arthritis, and Crohn disease. *Multiple sclerosis (MS).* Evidence continues to accumulate supporting a protective role for vitamin D in its risk and progression. Notable recent findings are that high 25(OH)D levels at the time of a first demyelinating event predicts a lower MS risk and a decreased risk of them in offspring whose mothers had high 25(OH)D levels. High doses of vitamin D3 (up to 280,000 IU/ wk for 6 weeks) have been used safely in patients with MS(13). The progression and activity of MS were not affected, but the number of gadolinium-enhancing lesions per patient assessed by nuclear magnetic brain scan was significantly reduced. *Rheumatoid Arthritis (RA)* is an autoimmune disorder of unknown etiology in which both genetic and nonge-

netic factors contribute to disease susceptibility. Studies showed that when confronted by an inappropriate and overly exuberant immune response, vitamin D may act in a paracrine manner to decrease T cell responsiveness through the inhibition of cellular proliferation and reduction in lymphokine production (12). Vitamin D deficiency is prevalent in *Crohn's Disease*. It is an inflammatory bowel disease which often leads to osteopenia and osteoporosis due to malabsorption of vitamin D.

Cancers. Association studies have related higher serum levels of 25(OH)D to reduced incidence of many types of cancers. It has been hypothesized that the local conversion of 25(OH)D to 1,25(OH)2D in healthy cells in the colon, breast, and prostate can help prevent malignancy by inducing cellular maturation, inducing apoptosis, and inhibiting angiogenesis while enhancing the expression of genes including P21 and P27 to control cellular proliferation (4,7). A reanalysis of the WHI concluded that in 15,646 women (43%) who were not taking personal calcium or vitamin D supplements at randomization, the calcium and vitamin D intervention significantly decreased the risk of total, breast, and invasive breast cancers by 14% to 20% and the risk of colorectal cancer by 17% (16). Higher dietary intake of vitamin D had a progressively lower risk of pancreatic cancer compared with those who had the lowest intake.

Cardiovascular disorders. Observational studies in humans found that 25(OH)D and 1,25(OH)2D levels are inversely related to coronary artery calcifications and are lower in patients with myocardial infarction(17). An *in vitro* study suggested that low 25(OH)D levels influence the activity/expression of macrophages and lymphocytes in atherosclerotic plaques, thus promoting chronic inflammation in the artery wall. A short course of treatment with vitamin D (4000 IU for 5 days) effectively attenuated the increase in circulating levels of inflammatory cytokines after an acute coronary event. These findings provide support for the anti-inflammatory effects of vitamin D on the vascular system and suggest mechanisms that mediate some of its cardioprotective properties. Observational studies indicated that a serum 25(OH)D level less than 30 ng/mL was strongly associated with hypertension and metabolic syndrome. This effect is thought to be partly mediated through regulation of the renin-angiotensin aldosterone axis.

Diabetes mellitus and metabolic syndrome. Children with vitamin D deficiency or insufficiency had a 2.5-fold higher risk of an elevated blood glucose level, a 2.4-fold increased risk of elevated blood pressure, and a 4-fold increased risk of metabolic syndrome, a prelude to type 2 diabetes. A meta-analysis of 11 prospective studies provided the association between circulating 25(OH)D levels and type 2 diabetes. It suggested a strong inverse association between serum 25(OH)D concentration and incidence of type 2 diabetes, but no evidence of a beneficial effect of vitamin D supplementation on type 2 diabetes (7).

Respiratory tract diseases and wheezing disorders. Children with rickets were at higher risk for upper respiratory tract infections and for dying of them (13). Macrophages have a VDR, and when they ingest an infectious agent, such as tuberculosis bacillus, the toll-like receptors are activated, resulting in signal transduction to increase the expression of VDR and

CYP27B1(7). High 25(OH)D levels during maternity were associated with a decrease in childhood wheezing by nearly 50% compared with low maternal 25(OH)D levels. Newborns with 25(OH)D levels less than 10 ng/mL were twice as likely to develop respiratory tract infections compared with those with levels of 30 ng/mL or greater.

Neurologic disorders. The brain has a VDR and has the ability to produce 1,25(OH)2D3. *In vivo* mouse studies found that *in utero* hypovitaminosis D impairs brain development and leads to persistent changes in the adult brain. There is minimal evidence for an association of low maternal vitamin D status with risk of autism. The 1,25(OH)2D3 seems to have a neuroprotective role, inducing remyelination by endogenous progenitor cells and stimulation of amyloid-b clearance by macrophages of patients with Alzheimer disease.

Mortality. Vitamin D deficiency is associated with an increased risk of total mortality. Most, but not all, studies documented increased mortality rates in patients with low 25(OH)D concentrations. In a recent meta-analysis with 70,528 randomized participants (86.8% females) with a median age of 70 years, vitamin D supplementation with or without calcium reduced mortality by 7%. However, vitamin D supplementation alone did not affect mortality, but risk of death was reduced if vitamin D was given with calcium (12, 13).

TREATMENT AND PREVENTION OF VITAMIN D DEFICIENCY

The source of vitamin D in humans is sun exposure. Although excessive exposure to sunlight increases the risk of non melanoma skin cancer, which is easy to detect and easy to treat. Time of day during *sun exposure*, season, latitude, and degree of skin pigmentation dictate how much vitamin D3 is produced during sun exposure. For a white person, if 30 minutes of June noontime sun would cause a mild sunburn, then 10 to 15 minutes of exposure followed by good sun protection should be sufficient to produce adequate vitamin D. Very few *foods* naturally contain vitamin D. *Foods fortified* with vitamin D usually contain 100 IU per serving. Food fortification with vitamin D (especially in milk) or some cereals, juices, other dairy products, some margarines, bread are effective in significantly increasing 25(OH)D levels in the population (18,19). *Vitamin D Supplementation***.** It is recommended 600 to 800 IU daily should meet the requirements to optimize bone health in most of the population, higher vitamin D intakes (1000-2000 IU) are needed to reach and maintain 25(OH)D levels greater than 30ng/mL (20). An effective strategy to treat vitamin D deficiency and insufficiency in children and adults is to give them 50,000 IU of vitamin D2 once a week for 6 and 8 weeks, respectively (20).

To prevent recurrence of vitamin D deficiency in children, administration of 600 to 1000 IU/d is effective. For adults, to prevent recurrence of vitamin D deficiency, administration of 50,000 IU of vitamin D2 every 2 weeks is effective (19,20).

Pregnancy and lactation. The 25(OH)D passes from the placenta into the bloodstream of the fetus. Because the half-life for 25(OH)D is approximately 2 to 3 weeks, the infant can remain vitamin D sufficient for several weeks after birth, as long as the mother is vitamin D sufficient. Maternal supplementation with 2000 and 4000 IU/d of vitamin D during pregnancy

improved the maternal/neonatal vitamin D status. Human breast milk and unfortified cow's milk have little vitamin D (21). Only after lactating women were given 4000 to 6000 IU/d of vitamin D was enough vitamin D transferred in breast milk to satisfy the infant's requirement (21).

Vitamin D supplementation in special conditions. Because body fat can sequester vitamin D, it is now recognized that children and adults who are obese require 2 to 5 times more vitamin D to treat and prevent vitamin D deficiency. Patients taking antiseizure medications, AIDS medications, and glucocorticoids often require more vitamin D to satisfy their requirements. *Type of Vitamin D Supplementation*: Either vitamin D2 or vitamin D3 can be used for vitamin D supplementation, although there is controversy regarding vitamin D3 vs vitamin D2 for achieving and maintaining higher serum 25(OH)D levels. Although a recent meta analysis indicated that vitaminD3 is more efficacious than is vitamin D2 (7).

Safety and intoxication. Vitamin D intoxication is characterized by hypercalcemia, hypercalciuria, and hyperphosphatemia, which, in turn, are responsible for soft-tissue and vascular calcifications and nephrolithiasis in the long term. Serum 25(OH)D levels are usually markedly elevated (>150 ng/ mL) in individuals with vitamin D intoxication. Daily doses of vitamin D3 up to 10,000 IU were safe in healthy males, and there was no evidence of hypercalcemia or hypercalciuria for 5 months (22). Higher doses of vitamin D (up to 40,000 IU/d) are still safe provided that a serum 25(OH)D concentration of 200 ng/mL is not exceeded.

CONCLUSIONS

A sufficient Vitamin D status might be beneficial regarding bone, cardiovascular and overall health. Vitamin D deficiency is a common underdiagnosed condition that has received increasing attention in the world. Vitamin D deficiency during pregnancy may adversely influence placental development and fetal programming. An effective strategy to prevent vitamin D deficiency and insufficiency is to obtain sun exposure, ingest foods that contain vitamin D, and take a vitamin D supplement to increasing serum 25(OH)D levels above 30 ng/mL.

ELECTROCARDIOGRAPHIC CHANGES IN ENDOCRINE DISORDERS (Abstract): Cardiovascular abnormalities associated with endocrine diseases are often frequent and due to complex relationships between endocrine glands (with internal secretion) and cardiovascular system (heart and vessels). Certain hormones secreted by the endocrine glands (particularly the thyroid and pituitary gland) excesses or deficiencies, are involved in morphogenesis, growth processes and activity regulation of cardiovascular system, most often in connection with the autonomic nervous system. There are also a lot of electrocardiographic changes caused by hormonal disorders that requires differential diagnosis and represents the source of erroneous diagnosis. Endocrine pathology occurred later than a heart disease, may worse heart function. Ignoring the cardiovascular events that may occur in the evolution of endocrine diseases, may induce increased mortality due to cardiovascular complications. **Keywords:** ENDOCRINE DISEASES, ELECTROCARDIOGRAM, RHYTHM TROUBLES.

Endocrine pathology offers a large broadband of multiple interference and implications in cardiovascular pathology. These connexions are supported by complex relationships between endocrine glands (with internal secretion) and cardiovascular system (heart and vessels). It is well known that certain hormones secreted by the endocrine glands (particularly the thyroid and pituitary gland) are involved in morphogenesis, growth processes and activity regulation of cardiovascular system, most often in connection with the autonomic nervous system (1, 2).

This complex relationship between endocrine and cardiovascular pathology is not new.

In 1835, Robert Graves (one whose name will carry disease - Basedow Graves) described...*"Three cases of prolonged violent palpitations in women with thyrotoxicosis..."*. Twenty years later, in 1855, Thomas Addison described in a highly suggestive phrase (which later would clearly outline the clinical picture of the disease)... *"patients with small adrenal capsule have weak and compressible pulse and as a progress of the disease, the body loses weight, pulse becomes smaller and weaker, and the patient, after a long time and grad-*

ually falls off... ".

Therefore since the mid-nineteenth century were known or suspected effects of thyroid hormone and adrenal gland diseases of the cardiovascular system (2).

The problem is up-dated now. A meta-analysis published in 2007 in the European Journal of Endocrinology emphasized that thyroid hormone excess would increase cardiovascular mortality of about 1.7 times. Another study published in 2011 confirmed the same fact, speaking about increasing cardiovascular mortality with 20% in persons with hyperthyroidism.

The interrelations between endocrine and cardiovascular pathology are important due to several reasons: 1. The cardiovascular symptoms may mask the endocrine disease. This is the major source of confusion and diagnoses errors 2. After diagnosis, the endocrine disease will require specific treatment. 3.Ignoring the cardiovascular events that may occur in the evolution of endocrine diseases, may induce increased mortality due to cardiovascular complications. Endocrine pathology occurred later than a heart disease, may worse heart function. There are also a lot of electrocardiographic changes caused by hormonal disorders that requires differential diagnosis and represents the source of erroneous diagnosis (1, 3, 6, 20).

Pituitary gland pathology

The excess of growth hormone (GH) also has implications in cardiovascular disease. Acromegalic cardiomyopathy is the most severe form of cardiac damage. The main clinical aspects are: arterial hypertension and early atherosclerotic signs induced by acromegalic cardiomyopathy.

On ECG the main abnormalities are: left axis deviation, left ventricular hypertrophy with T-wave inversion, septal Q-waves, ST-T wave depression, abnormal QT dispersion and conduction defects that occurr in 50% of patients, left bundle-branch block, atrial and especially ventricular arrhythmias (induced by cardiac dilation). These changes are nonspecific. Moreover, sick sinus syndrome may be associated with acromegalic cardiomyopathy (1, 3, 4, 5, 7, 9, 10, 18).

Thyroid gland pathology

Thyroid hormones (thyrotoxicosis) excess induces both cardiac and vascular effects. The thyroid hormones activity may be performed through cardiac specific receptors or mediated by the sympathetic nervous system (which is over stimulated). The excess of thyroid hormones increases the metabolic needs of the tissues (high demand of oxygen in the peripheral tissues) (1, 2, 3, 21).

The main cardiac effects of excessive thyroid hormone are: increased contractility, automaticity and atrial excitability (with consequent risk of supraventricular arrhythmias) (2, 3, 19).

The vascular effects of thyroid hormones are: vasodilatation in skin and muscle and decreased peripheral vascular resistance (2, 3).

Cardiac manifestations of hyperthyroidism may be functional (as hyperkinetic syndrome) and organic (cardio thyreosis) (21).

Hyperkinetic syndrome - often brings the patient to the emergency room. The most common electrocardiographic abnormalities are: sinus tachycardia, hyper voltage, normal morphology of QRS complexes. Each of these entities has clinical and therapeutic particularities. Hyperthyroidism is considered an aggravating and precipitating factor of heart ischemia and heart failure.

As main characteristics:

- Atrial fibrillation from cardiothyreosis is first repetitive and then becomes permanent, with fast ventricular rate and resistance to digital treatment. The sinusal rhythm may be recovered only after achieving the euthyroidian status. Despite high ventricular rate, atrial fibrillation from cardio thyreosis is rarely followed by hemodynamic instability;

- Pectoral angina occurs frequently in patients with hyperthyroidism (hyperthyroidism aggravates or induces angina episodes) ; in some cases thyroid hormones may induce vasospasm in normal coronary artery. However, angina occurs in patients with subclinical coronary heart disease (coronary bed being affected by atherosclerosis, including microvascular injury);

- Hypothyroidism occurs due to insufficient synthesis, transport and / or reception of thyroid hormones. It's cardiovascular effects are mainly the consequence of decreasing metabolic needs of myocardial or peripheral tissues (vascular permeability and capillary growth);

- Electrocardiographic abnormality in hypothyroidism (for differential diagnosis in the clinical context) includes: sinus bradycardia, micro voltage, QT prolongation, conduction disturbances, changes in repolarization phase, T wave flattening (1, 2, 3, 5, 6, 9, 10, 11, 12, 17).

Parathyroid diseases

Hyperparathyroidism (excessive secretion of parathyroid hormone), have the following consequences: hypercalcemia, hypercalciuria, hypokalemia, and hyperphosphaturia. The calcium ion increases myocardial contractility and peripheral vascular resistance and induces nephrocalcinosis. Cardiovascular manifestations of hyperparathyroidism are very polymorphic: arterial hypertension, cardiac calcifications (may induce the occurrence of arrhythmias), accelerated atherosclerosis (pectoral angina, myocardial infarction) (23).

The characteristic ECG modification oh hypercalcemia is QT interval shortening but it may induce also severe conduction disturbances: total AV block and sinus arrest, ventricular arrhythmias (PVCs, ventricular tachycardia, ventricular fibrillation) and promotes digitalis intoxication complications.

Hypocalcemia from hypoparathyroidism induces electrocardiographic abnormalities, consisting of: QT prolongation (may induce malignant ventricular arrhythmias) and changes in repolarization phase (ST) without stretching T-wave. Rarely, hypocalcemia may induce dilated cardiomyopathy which becomes reversible once with serum calcium values control (1, 2, 3, 5, 6, 16).

Adrenal diseases

Their correlation with cardiovascular pathology is quite complex, due to the effects of both mineralocorticoid and glucocorticoid hormones.

Hypercortisolism (excessive production of glucocorticoid hormone- dependent or independent of ACTH) has as main cardiac manifestations: moderate arterial hypertension, accelerated atherosclerosis (at coronary level may produce angina attacks). The main ECG abnormalities is secondary left ventricular hypertrophy (related to arterial hypertension or coronary atherosclerosis) (3, 8). Arrhythmias are rare and usually occur on the background of hypertensive left ventricular hypertrophy. Hyperaldosteronism (primary or secondary excess of mineralocorticoid) may induce

cardiovascular emergencies, both related to secondary hypertension or severe hypokalemia (may cause severe ventricular arrhythmias). Severe hypokalemia induces ECG abnormalities: QT prolongation, abnormal repolarization phase (slight depression of ST segment, flat T waves), U waves in precordial leads, prolonged P and PR interval duration (first degree atrioventricular block), wide QRS complex, ventricular arrhythmias (ventricular extrasystoles, ventricular tachycardia with evolution through ventricular fibrillation refractory to defibrillation). The severity of ECG abnormalities correlates with low potassium level (14, 15, 22, 24).

Primary adrenal insufficiency (Addison's disease) has humoral response causing hypoglycemia, hyponatremia, hypochloremia, hyperkalemia. Cardiovascular consequences are represented by hypotension and syncope and specific electrocardiographic changes related to electrolyte disturbances. Hyperkalemia causes various ECG abnormalities related to potassium levels: sharp, narrow base T waves, intraventricular conduction abnormalities (large QRS complexes exceeding 0.12 seconds), left axis deviation and then the decrease of P wave until disappears, ST-segment abnormalities (pseudo - lesion), arrhythmias and atrioventricular conduction disturbances. At high potassium concentrations (above 7.5 mEq / l) - cardiac arrest (14, 15, 22, 24).

Pathology of the adrenal medulla

Pheochromocytoma - chromatin tumor of the adrenal medulla is characterised by excessive secre-tion of catecolamines (adrenaline and noradrenaline). The clinical manifestations are represented by paroxystic seizures, paroxystic or permanent hypertension, sometimes orthostatic hypotension, arrhythmias, angina episodes. Electrocardiographic abnormalities in pheochromocytoma are nonspecific: negative T waves, left ventricular hypertrophy, sinus tachycardia, short PQ interval, supra ventricular arrhythmia (atrial premature beats, paroxystic or permanent atrial fibrillation) (13).

Adrenergic myocarditis and cardiomyopathy have clinical manifestation as: left ventricular failure or cardiac asthma, pulmonary oedema or severe arrhythmia (atrial fibrillation, premature ventricular beats or ventricular tachycardia). All of them represents emergencies and requires specific therapeutic measures. All these clinical and electrocardiographic signs of pheochromocytoma disappear together with the removal of the tumor (13).

CONCLUSIONS

Electrocardiographic changes in endocrine disorders are quite frequent and may be provoked by hormone excess (ex. hyperthyroidism) or by secondary electrolites disturbances (hypokalemia associated with primary or secondary hyperaldosteronism). Sometimes these electrocardiographic changes may be related to other cardiac abnormalities – such as arterial hypertension or left ventricular hypertrophy often associated with acromegaly or pheochromocitoma. Ignoring the cardiovascular events that may occur in the evolution of endocrine diseases, may induce increased mortality due to cardiovascular complications. In the majority of cases these electrocardiographic signs disappear together with the treatment of endocrine disease.

PHARMACOTHERAPY VERSUS PSYCHOTHERAPY IN PANIC DISORDER.REVIEW (Abstract) Panic disorder is one of the most frequent psychiatric conditions and the incidence is increasing. More worrying than the number of patients is the major negative impact over personal, social and economic functioning. Due to the increasing risk of death, whether by suicide or by cardiovascular disease, in patients suffering of panic disorder a prompt, adequate intervention is essential. This condition has a chronic evolution, with low rates of remission and a significant negative impact over quality of life and over social and economic aspects. In this article we presented different aspects related to the therapeutic management of panic disorder, with special reference to pharmacotherapy and its specific classes and psychotherapy, particularly Cognitive-Behavioral Therapy. These two therapeutic categories proved to be the most efficient in both acute and long-term symptomatology, with improvement of anxiogenic rumination, avoidance behavior or agoraphobia. Pharmacotherapy, whether with antidepressants or benzodiazepines, is recommended to be followed by psychotherapy. SSRIs and SSNRs are recommended as first-line medication, while benzodiazepines are necessary only in acute phases or until the therapeutic effect of the above-mentioned medicines is obtained. In treatment-resistant patients at patients who do not respond sufficiently to any first-line treatments it is necessary to use other classes of medicines, such as atypical antipsychotics. **Keywords**: PANIC DISORDER, PSYCHOTHERAPY, COGNITIVE-BEHAVIOURAL THERAPY, PHARMACOTHERAPY.

Panic attack is one of the most important types of anxiety disorder. In Romania, due to the high level of risk, the acute episode of a panic disorder was included in the list of psychiatric emergencies, based on Order 488, point 159 of April 2016, from Mental Health Law. Since over 70% of the people who attempted suicide had an associated anxiety disorder, this Order is well justified. Panic attack is also independently associated with suicide risk, and comorbidity of panic attack with personality disorder is characterized by a higher risk of attempted suicide over either disorder alone (1, 2, 3, 4). Thus, anxiety associated with personality disorder was correlated with an increase in suicide attempt from 1.7 to 2.6 times (5).

Secondly, cardiorespiratory involvement in panic attack physiopathology can worsen its course or more, it can lead to death in population with the above-mentioned comorbidities (6,7,8). In the case of a cardiovascular disease, the anxiety symptoms in arrhythmic patients are associated with a higher severity of atrial fibrillation (9,10) and atrial fibrillation recurrence (10). Comparing the QT interval on electrocardiogram in a control group and patients suffering from panic disorder, Atmaca found that the QT in the latter group was significantly longer, prolonged QT being associated with arrhythmic events and sudden death (11).

In patients with panic disorders, the high risk of death, whether by suicide or cardiovascular disease, makes a prompt intervention mandatory.

Panic disorder has a chronic course and a low rate of remission with a significant negative impact not only on life quality but also on social and economic aspects (12,13).

Considering all these aspects, the main purpose of this article was to present data in the literature regarding different approaches of panic disorders, especially the adequate management of acute phase, which requires special emergency care. Therefore, the efficacy of pharmacological and psychological therapy, especially the cognitive behavioral therapy, used separately or combined will be analyzed.

To obtain the articles for this review, we searched PubMed using the following key words: “panic disorder”, “pharmacotherapy” and “psychotherapy”. The accepted studies were only those comparing pharmacological therapy with psychotherapy.

First line treatment

First line treatment of panic disorder is represented by selective serotonin reuptake inhibitors (SSRIs) and serotonin and norepinephrine reuptake inhibitors (SNRIs). According to meta-analyses and randomized clinical trials, Citalopram, Fluoxetine, Fluvoxamine, Paroxetine, Sertraline and Escitalopram are the first therapeutic option (5).

A study of Azhar (14) compared the efficacy of Fluvoxamine treatment alone and Fluvoxamine combined with Cognitive Behavioral Therapy (CBT) and CBT alone. The best results were obtained by combining the two therapeutic methods, with significant improvement of the following parameters tested before and after nine weeks of treatment: frequency of panic attacks reduced from 16.7 to 4.07 per week, catastrophic belief score from 100 to 31.79 and the scores from Hamilton Anxiety Rating Scale reduced from 37.14 to 22.86. The group that received only CBT obtained similar results, sometimes even better than the others for the above-mentioned variables. The Fluvoxamine alone group had the lowest scores for the mentioned parameters, therefore psychotherapy is essential for improving anxiety symptoms.

Venlafaxine, an SNRI, is also efficient in reducing the severity of panic disorder symptoms (5).

Treatment with Benzodiazepines

In the acute phase of a panic disorder, benzodiazepines are the most frequent recommended medicines. Their main advantage is represented by the short period of time necessary to achieve the therapeutic effects.

Watanabe et al. (15) presented the benefits of benzodiazepine therapy versus combined benzodiazepines and behavioral therapy. The conclusion is that the combination therapy might be superior to behavior therapy alone in terms of the global severity of symptoms, phobic avoidance behavior and social functioning.

In acute phase, combined therapy is ef-

ficient in reducing the frequency of panic attacks. On long term, six to twelve months after treatment completion it was noticed that psychotherapy alone is superior to the one that associates benzodiazepines (15). This situation can be explained by the fact that long-term administration of benzodiazepines causes cognitive dysfunction (16). Besides that, it is required to use them for short periods and in minimal doses (17) because this class of anxiolytics increases the risk of dependence and relapse (12).

Considering that panic disorder is characterized by catastrophic beliefs about the physical, mental or social consequences, the associations with drugs that diminish the cognitive capacity will only emphasize the anxiogenic ruminations and thus will have a negative impact on disorder course (17).

Management of treatment-resistant panic disorders

Panic disorder consists of recurrent paroxysmal panic attacks, along with the worry regarding future panic attacks and phobic avoidance behavior. Over 50% of patients on treatment continue to experience panic attacks symptoms and fail to obtain remission. Half of the cases that do remit will present relapses later in life (18).

Two types of criteria regarding remission of panic disorder have been proposed (19,20). The first criteria include: absence of panic attacks, absent or reduced agoraphobic avoidance behavior, Hamilton Anxiety Score (HAMAS)≤ 7-10, absence of functional impairment, absent or reduced depressive symptoms, Hamilton Depression Scale (HAMDS) ≤ 7. The second criterion includes the following elements: Panic Disorder Severity Scale (PDSS) ≤ 3 and HAMDS ≤ 7. Treatment resistance is defined as the failure to meet any of the above-mentioned remission criterion after at least six months of optimal treatment (19,20).

According to Mu-Hong and Shih-Jen (18) recommendations, CBT or pharmacotherapy should be the first option in panic disorder treatment, while combining the two of them should be indicated as second-line and administered to patients resistant to treatment. If favorable results are not obtained with any of these strategies, augmentation with atypical antipsychotics is an established drug treatment strategy. From this category Aripiprazole, Quetiapine and Olanzapine proved to increase the efficacy of baseline antidepressant treatment. The results with using other drugs, such as GABAergic antiepileptics, D-cycloserine and anti-inflammatories are inconsistent and need additional evidence to sustain their inclusion in the treatment of treatment-resistant panic disorders.

CBT or/and pharmacotherapy

Even though some studies support the superiority of CBT over pharmacotherapy (21), it is generally accepted that their combination is more effective than CBT alone. A global improvement of symptoms but without an improvement on quality of life had been recorded. However, when long-term outcomes were examined combining CBT with pharmacotherapy proved unsatisfactory. The negative effects can be explained by the fact that the learning process during CBT is influenced by drug therapy (12), especially with benzodiazepines, which on long term had been associated with impairment of cognitive function (15,16). In the study by Krysta et al. (16) the anxiolytic agent is represented by Escitalopram and Duloxetine, which improve attention and executive function, Tianeptine, which improves attention and short-term memory, and Sertraline and Mirtazapine.

Meuldijk et al. (22) suggest that concise care with CBT and/or pharmacotherapy (three months) has similar outcomes as

classic therapy, which requires a longer period of treatment of three or six months to one year or even more. This approach involves 45-minute weekly CBT sessions for seven weeks consecutively. Following this method, the clinical results are obtained earlier, and patients are more satisfied with this type of care.

Treating panic disorders with CBT has certain advantages to pharmacotherapy: fewer side effects, lower relapse rate, and a higher rate of treatment adherence. Pharmacological treatment has many side effects and the risk of relapse is higher, resulting in discontinuation of treatment. In practice CBT is less used than pharmacotherapy especially due to the lower availability of specialized personnel (23, 24). Having patients repeatedly confront safe, but anxiogenic situations, as it happens in exposure therapy, results not only in a reduction in frequency of panic attacks but also a reduction of the fear of having another panic attack, compared to the administration of drugs alone which only reduces the frequency of attacks (21).

At the basis of these results stands the neurobiological change, which appears secondary to the psychotherapy. In panic disorder there is an improper cortical inhibition, for example from prefrontal cortex to an overactive limbic system, from amygdala and insular cortex and a poor modulation to the hippocampus (18). In the case of patients who followed CBT, exposure to anxiogenic situations did not over activate the amygdala. This deactivation represents a more efficient control over limbic system to the prefrontal cortex, which manages more efficiently anxiogenic triggers, by more rational analyze of the exposure (21).

Initiation of whichever therapy requires careful analysis of individual characteristics of patients with panic disorder. Therefore, CBT should be taken in consideration as first option in patient who, for example, worry excessively about or cannot tolerate the side effects of prescribed medicines. On the other hand, pharmacotherapy can be considered as first-line strategy for a patient who presents more somatic symptoms (palpitation, paresthesia, sweating etc.) than cognitive ones (persisting fear for not experiencing another panic attack) (18, 25, 26).

From our review and summing up all the studies above presented, in the treatment of panic disorder we can used pharmacotherapy, whether antidepressants or benzodiazepines, but it is recommended to be associated with psychotherapy. As first line treatment it is recommended selective serotonin reuptake inhibitors or serotonin and norepinephrine reuptake inhibitors, while benzodiazepines are necessary only in acute phase or until the first two treatment lines determined a therapeutic effect. For the resistant cases, it is required to use other group of drugs such as atypical antipsychotics.

IRON HYPOTHESIS OF CARDIOVASCULAR DISEASE: STILL CONTROVERSIAL (Abstract): Iron hypothesis has been a controversial subject for over 30 years as many studies support its role as a risk factor for cardiovascular disease, while other studies found no evidence to support it. The conflicting results are accounted for by the non-homogeneity of trial design in terms of population inclusion criteria and different endpoints, non-uniform use of parameters for assessing iron role, and incomplete understanding of the mechanisms of action. The nature of iron is dual, being of crucial importance for the human body, but also toxic as "free iron" induces oxidative stress. Under physiological conditions, there are efficient and complex mechanisms against iron-induced oxidative stress, which could be reproduced for creating new, intelligent antioxidants. Iron depletion improves the cardiovascular prognosis only if serum concentration is at the lowest limit of normal ranges. However, low iron levels and the type of dietary iron intake correlate with atherosclerotic cardiovascular disease, influence the ischemic endpoints in the elderly, and exert negative impact on heart failure prognosis. So far, the causal relation and involved mechanisms are not fully elucidated. Iron overload is a difficult and frequent condition, involving the cardiovascular system by specific pathogenic pathways, therefore determining a particular form of restrictive cardiomyopathy and vaso-occlusive arterial damage. **Keywords**: IRON HYPOTHESIS, OXIDATIVE STRESS, CARDIOVASCULAR DISEASE, IRON DEFICIENCY, BODY IRON STORES

IMPORTANCE OF IRON IN THE HUMAN BODY

Although the total amount of human body iron is very small (4-5 g), it is of vital importance. Iron is a metabolically active micronutrient with the unique property to donate and accept electrons, so it exists in a range of oxidation states, the most common being the bivalent or ferrous (Fe^{2+}) and trivalent or ferric (Fe^{3+}) forms. The human body uses this property in the main enzymatic and non-enzymatic cellular processes. Dietary iron is absorbed mainly by duodenal enterocytes using specific transmembrane transport mechanisms, depending on the heme or non-heme iron form. Systemic iron metabolism regulation is controlled by hepcidin through the specific receptor ferroportin which optimizes and synchronizes its prompt use, preserves iron stores, and prevents uptake by enterocytes. Over 80% of circulating iron is directed to hemoglobin synthesis, whereas the remaining 5-15% provides structure and function

to various enzymatic proteins (cytochromes, myoglobin, iron-sulfur complexes). Therefore, iron is involved in the proper oxygen transport and storage, regulation of cellular energy processes, cellular apoptosis and growth, inflammation, gene regulation, DNA and neurotransmitter synthesis, myogenesis, and xenobiotic metabolism. The action of iron is achieved by binding to transferrin, the specific "carrier" which delivers it to target cells using soluble receptors – sTfR. In the absence of a physiological pathway for excretion, iron excess is stored as ferritin (10-20%), mainly in the liver, spleen and bone marrow cells. Intracellular iron metabolism is regulated by a complex regulatory protein system (1, 2).

IRON HYPOTHESIS

The role of iron in cardiovascular disease was first mentioned in the '60s, when the relationship between iron deficiency anemia in inflammatory diseases and heart failure (HF) was postulated, but the issue was abandoned (3, 4). The American researcher and clinician Jerome L. Sullivan is the first to rediscover and theorize this relationship based on a series of clinical observations, namely that HF is usually a rule in iron overload diseases, and iron stores are higher in men and post-menopausal women. Sullivan gathered these observations in the "iron hypothesis" published in 1981. This hypothesis states that postmenopausal women are at higher risk for cardiovascular disease not only by changing their hormonal profile, but also due to the accumulation of stored iron with age (5).

Based on studies available at that time (6, 7), Sullivan proposes a new paradigm that iron may modulate the ischemic risk and atherogenesis through a unifying mechanism (8). The pathogenic mechanism of the paradigm is oxidative stress. Iron has the propensity of binding reactive oxygen species through Fenton reaction: $Fe^{2+} + H_2O_2 = Fe^{3+} + OH^- + HO^\cdot$ and Haber-Weiss reaction: $O_2^{\cdot -} + Fe^{3+} = O_2 + Fe^{2+}$. Hydroxyl radical ($HO^\cdot$) resulting from these reactions is most harmful to cells and tissues. However, the cytotoxic potential of iron is possible only in case of free iron, also known as "serum catalytic iron". Under physiological conditions, the human body neutralizes free iron by its complete binding to transferrin and ferritin. Any situation in which storage capacity is exceeded or there is an inadequate iron supply will result in overproduction of reactive oxygen species, with cytotoxic effect on cardiomyocyte and arterial wall. The relationship is bidirectional because vascular inflammation, common in cardiovascular disease, also induces oxidative stress. The consequence is the stimulation of iron release from ferritin and low affinity of transferrin for iron, namely generation of circulating catalytic iron. The mechanism of action of free iron on arterial vessel is the subject of numerous experimental studies. Some studies show that iron induces endothelial dysfunction, the promoter of atherosclerosis (ATS). In an original study, Kartikasari et al. noticed the increasing rate of monocyte adhesion to human umbilical endothelial cells treated with serum from patients with hemochromatosis, followed by the expression of adhesion molecules (VCAM, ICAM, E-selectin) in direct relation to the level of free iron (9). Recently, in a study investigating endothelial dysfunction and inflammation induced by iron oxide nanoparticles, Zhu et al. confirmed the toxic action of catalytic iron on human aortic endothelial cells. The authors suggested that the

interaction was mediated by monocytes that release free iron through phagocytosis, but the nanoparticles also have a direct structural and functional cytotoxic effect on vascular endothelium (10). An interesting observation reported by other studies on iron deficiency is the increase in nitric oxide production and iNOS synthase activity that paradoxically alter the intracellular metabolism and induce the release of catalytic iron (1, 10). The relationship with the initiation of atherogenesis is another process demonstrated in the 80's and is based on LDL oxidation and formation of fatty streaks, as the earliest stage in atheroma plaque formation. Recent studies also support iron intervention in ATS progression. Exposure of red blood cells to oxidized plaque material induces erythrocyte lysis and generation of ferrohemoglobin, which is converted by oxidation to feri- and ferilhemoglobin. This chain of chemical reactions destabilizes the heme group that is oxidatively cleaved and releases iron. Thus, plaque lipid oxidation is a feed-forward process which promotes atheroma development, while free iron exerts its cytotoxicity on endothelial cells. Interestingly, the lipids of atheroma plaque isolated from the arterial vessel are not harmful to endothelial cell, while the exposure to red blood cells induces cytotoxicity (11).

LESSONS FROM CLINICAL TRIALS

Iron hypothesis is even today a topic of debate and controversy as there are numerous studies that equally support or deny the initial view. The first remarkable study that supports the iron hypothesis is KIHD, a Finnish prospective trial that investigated over 5 years a cohort of 1,931 men aged between 42 and 60 who had no symptomatic ischemic heart disease (IHD) at entry (12). The conclusion is that serum ferritin level $\geq$ 200 μg/L (considered to be normal) in subjects with high dietary intake of red meat is associated with a 2.2-fold higher risk of acute myocardial infarction (AMI), and the effect is enhanced by LDL-cholesterol. The findings of this reference study are also supported by the Rotterdam trial (13). It supports the relationship with the risk of AMI in the elderly, but again emphasizes the synergistic role of serum ferritin and cardiovascular risk factors, like diabetes, smoking, high LDL-cholesterol. As there are many conflicting data, two recent meta-analyses synthesized the information regarding the relationship between IHD and ferritin level (11,337 patients) or total iron-binding capacity with transferrin (14, 15). The conclusion is that each 50 μg/l increase in ferritin above the level of 200 μg/l increases by 2.4% the IHD risk, and the effect is synergistic with other cardiovascular risk factors (14). As to transferrin, considered an antioxidant molecule due to its ability to bind free iron, an inverse relationship between its level and IHD risk was found (15). The role of ferritin in promoting atherothrombosis is demonstrated by studies focused on the risk of carotid disease. SHIP study suggests a relationship with the prevalence of carotid damage in 2,443 participants recruited from the general population (16). The results are in agreement with the Bruneck study, the first of this kind, in which ferritin is considered to be one of the strongest predictors of incidence and progression of preexisting carotid lesions assessed by ultrasonography for 5 years, its effect being also amplified by LDL-cholesterol (17).

However, there are just as many studies suggesting that iron has a neutral effect on

cardiovascular risk (18). Meta-analyses and studies offer several explanations for these conflicting results (19). The first would be non-homogeneous study design related to different inclusion criteria, cutoffs used to define iron deficiency/overload, various end-points such as all-cause mortality, IHD, AMI mortality, stroke. A second key issue arises from the method to assess iron status (in most studies by measurement of ferritin, but also serum iron, transferrin saturation, dietary iron intake etc) and the interpretation of results (related to the impact of other risk factors). A good example is the study conducted by Sung et al. showing that ferritin is independently correlated with early coronary ATS estimated by calcium score, when not only the influence of traditional risk factors but also transferrin, markers of inflammation, and other risk factors are eliminated (alcohol, diet, type of physical activity, components of the metabolic syndrome) (20). The limits of interpretation might be related to the markers used to define iron role. For example, currently there are only two epidemiological studies using the sTfR/ferritin ratio, considered optimal for iron status description in the human body. These studies noted the weak but consistently positive relationship with the risk of carotid ATS or the occurrence of a first AMI (21, 22). A promising perspective is the use of catalytic iron as a marker of cardiovascular risk, based on observations of two recent studies (23, 24). Rajapurkar et al. support both the relationship between catalytic iron levels and the prevalence of cardiovascular disease and its importance in acute coronary syndromes (25). The 10-month follow-up of a cohort of 1,701 patients with acute coronary syndromes concluded that the new marker is able to detect early a heart attack (within 3 hours of the onset of chest pain) and to identify the high-risk subgroup for all-cause mortality (3.97-fold) and adverse cardiac events apart from traditional risk factors. Finally, the results could be influenced by information related to the mechanisms of action of iron, insufficiently used in studies. For example, there are voices that argue that iron does not increase the cardiovascular risk directly but by amplifying the harmful vascular effects of homocysteine, assessed by flow-mediated vasodilatation (26). In an article published this year, Hsieh et al. report remarkable findings regarding hepcidin, which acts as an intrinsic cardiac hormone with a predominantly local effect. The authors note increased hepcidin levels in human cardiomyocytes pretreated with ferrous iron, which has a cytotoxic effect. The conclusion elegantly demonstrates that hepcidin can protect cardiomyocytes from iron-induced apoptosis through the extrinsic apoptotic pathway and GATA-4/Bcl-2 inactivation, a myocardial survival factor (27). Therefore, hepcidin contributes to the maintenance of myocardial structure. This study completes and offers a molecular explanation for previous data regarding the low level of hepcidin and increased 3-year mortality in HF or its correlation with increased left ventricular mass (28). On the other hand, there are observations on upregulation of hepcidin specific to ischemic myocardium after myocardial infarction (29). In the light of the study by Hsieh, it can be speculated that increased levels of hepcidin have the potential to diminish catalytic iron cytotoxicity derived from oxidative stress, thus limiting the infarct size (27). Finally, an interesting conclusion is that chemotherapeutic agents such as daunorubicin and doxorubicin induce cardiomyopathy by the same mechanism of iron-induced GATA-4 inactivation, namely feroptosis.

SERUM IRON LEVEL – PROTECTOR OR RISK FACTOR?

Based on the results of studies supporting the role of ferritin as a cardiovascular risk factor at levels close to the upper limit of the normal range, Sullivan launches a new assertion on the possible protective role of iron depletion against ischemic events, ATS lesions included (30). Salonen supports the idea reporting the reduction of the risk of ischemic events in all arterial areas, and of the number of revascularization procedures (12), and Meyers demonstrates the reduction of the risk of fatal AMI in men blood donors versus non-donors (31). Latest data from the multicenter controlled randomized trial conducted at the Department of Veterans Affairs Cooperative Studies Program on 1,277 patients with stable symptomatic peripheral arterial disease also suggest that reducing iron stores could improve the clinical evolution in certain subgroups of patients – young, smokers with low average concentrations of ferritin (32). Basically, iron depletion improves the cardiovascular prognosis only if serum concentration is at the lower limit of normal ranges.

Iron deficiency is well-documented to be associated with increased cardiovascular risk. Recent studies support the relationship with the high prevalence of IHD and carotid ATS, the influence on the ischemic endpoints in the elderly (33, 34), and its prognostic role in HF (35). The unsolved problem remains whether serum iron is causally related to cardiovascular disease, or is only a marker of chronic diseases associated with cardiovascular risk (19). Iron deficiency causes thrombocytosis associated with the risk of thrombotic complications (36), hypercoagulable state due to reduced deformability of microcytic erythrocytes, and increased viscosity (19). Finally, an important mechanism is iron deficiency anemia, a pejorative factor in the higher incidence and progression of chronic HF (2). Anemia in HF is the consequence of absolute iron deficiency resulting from decreased dietary intake, impaired intestinal absorption and transport mechanisms, blood loss after antiagregant and anticoagulant medication, abnormal hepcidin regulation etc. At the same time, HF is a state characterized by inflammatory status associated with increased levels of pro-inflammatory cytokines and oxidative stress. Inflammation leads to inadequate iron supply to meet the demand despite normal body stores, a condition called functional deficiency. Renal impairment and associated infections maintain inflammation and consequently iron deficiency. The fact is that anemia causes hypoxia, which induces increased nitric oxide concentrations causing vasodilatation and low blood pressure. It results in sympathetic stimulation that causes change in renal hemodynamics with decreased glomerular filtration rate, stimulation of renin-angiotensin-aldosterone system, and ADH secretion. The consequence is fluid retention and plasma volume expansion with a negative impact on the structure and function of the heart. Heart dilatation, increased ventricular mass, and apoptosis of cardiomyocytes are common events associated with cardiac dysfunction (35). Therefore, the association of anemia with HF and renal dysfunction (cardio-renal syndrome) is suggestively called the "triangle of death" (37). Despite this well-known pathogenic substrate, iron deficiency in HF was less studied. Opasich et al. noted that 20% of patients with systolic HF had absolute iron deficiency microcytic anemia, but in

57% of patients it was due to functional iron deficiency (38). Shortly after, Nanas published the only study to date in which iron deficiency was assessed by the standard method, bone marrow biopsy, and reported a high percentage (73%) in patients with advanced HF (39). Until now, only two observational studies reported the incidence of iron deficiency in the general population with HF, which seems to be more common in women, in advanced stages of disease with high NT-proBNP and C-reactive protein levels (40, 41). The fact remains that iron deficiency with or without anemia affects the myocardium and skeletal muscle, both organs having increased energy needs dependent on iron normal metabolism. Experimental data show that the myocardial molecular consequences are an increased expression of natriuretic peptides (ANP, BNP) and hepcidin, extracellular matrix remodeling, mitochondrial dysfunction, apoptosis, and reduced expression of TfR-1 (2,42). In the skeletal muscle, iron deficiency causes low oxygen transport and diffusion, decreased oxidative capacity, abnormal use of energy sources represented by glucose and fatty acids (2). The clinical consequence is decreased exercise ability. Also interesting are the clinical data that support the correlation with the risk of depression, predominantly in males (41). Also important is the negative impact on prognosis, iron deficiency being a strong predictor of the need for transplantation and 3-year risk of all-cause mortality (41, 43). On the other hand, the findings of seven studies on iron supplementation benefit in these patients are promising (2). Although the number of patients included is small, the follow-up period is short, and study design is heterogeneous, there is the assumption that iron deficiency should become a therapeutic target in HF. Its correction improves exercise ability, NYHA class, systolic dysfunction assessed by echocardiography, and mortality. FAIR-HF trial, the only multicenter placebo-controlled study that included both patients with and without anemia followed for 24 weeks, supports the beneficial effect of i.v. iron supplementation regardless of NYHA class, HF etiology, co-morbidities, hemoglobin level, with important impact on rehospitalization rate and good clinical tolerance (44). Similarly, a meta-analysis by Hunnicutt et al. published this year suggests that the incidence of IHD is related to low iron concentration and dietary heme iron intake. The causal relationship and the mechanisms involved remain to be elucidated (45). Lapice believes that the relationship with morbidity and mortality from IHD is not directly related to iron, but to dietary and lifestyle behaviors (smoking, alcohol consumption, level of physical activity) that can modulate the risk. For example, red meat containing heme iron has high levels of saturated fats and other oxidants (19).

Iron overload is a much more difficult to handle both clinically and therapeutically and the cardiovascular involvement is demonstrated by such iron storage diseases as hemochromatosis. In practice, there are also frequent conditions which require repeated blood transfusions, causing iron accumulation (hemosiderosis) in the absence of physiologic iron excretion mechanism. A unit of blood is equivalent to a dietary intake of 200 mg iron. A total body iron of over 7 g, corresponding to 30-50 units of red cells, can lead to signs of tissue toxicity. For this reason, it is necessary to monitor serum ferritin levels and at > 1000 μg/l, iron phlebotomy and chelating therapy become man-

datory (46). The cardiac response to iron overload is cardiomyopathy, typically developing in two stages - initially restrictive cardiomyopathy caused by fibrosis and myocardial ischemia invariably progressing to dilated cardiomyopathy with severe biventricular impairment (47). Diastolic dysfunction is considered an independent prognostic marker for the increased mortality rate in this category of patients. The pathophysiology of iron overload cardiomyopathy is mediated by oxidative stress that enables ischemia-reperfusion lesions even in the presence of normal coronary arteries. Specifically, iron regulates excitation-contraction coupling in cardiomyocytes via action on L-type Ca^{2+} channels, thereby causing diastolic and systolic dysfunction (48). Associated chronic tissue iron deposition and its electrophysiological effects determine interstitial fibrosis and cardiac specific conduction system damage, the cause of arrhythmias with prognostic impact. On the other hand, oxidative stress causes vascular impairment secondary to endothelial dysfunction and vascular stiffening (49). Iron overload also determines vaso-occlusive pulmonary disease with secondary pulmonary hypertension. Overall, vascular damage enhances heart dysfunction. Given high level of oxidative stress, antioxidant agents together with iron chelating agents is the rational therapy in these patients. Experimental studies suggest a cardiac protective role of taurine. A promising perspective is the use of Ca^{2+} channel blockers, especially of amlodipine, due to its coronary vasodilator and antioxidant action, but also the specific mechanism of iron action on L-type Ca^{2+} channels (50).

Even if the direct role of iron as a risk factor for cardiovascular disease is unclear, oxidative stress caused by catalytic iron is a certainty. Nature has effective weapons against this mechanism in physiological conditions, as is the formation of specific complexes (complex 1-Fe) with antioxidant role. The therapeutic use of this mechanism is considered by Gross`s team as innovative as these complexes could form the basis of the future design of "intelligent antioxidants". The authors demonstrate the mechanism of these complexes, which are bipolar, that is they can bind to both types of lipoproteins, LDL and HDL. The consequence is the catalytic decomposition of harmful species, i.e. permanent and targeted replacement of oxidized environment, in contrast to current antioxidants which have limited effect on reactive oxygen species and can damage the arterial wall. An interesting remark of the study is that directing the bivalent ferrous iron to these complexes by specific enzymatic methods may increase the antiatherogenic effect of HDL-cholesterol (51).

UPDATES IN THE PATHOGENESIS AND DIAGNOSIS OF HEPATIC ENCEPHALOPATHY (Abstract): In the pathophysiology of hepatic encephalopathy (HE), a serious complication of liver cirrhosis, different hypotheses, including increased blood ammonia levels, increased production and absorption of intestinal bacterial products are discussed. Recent studies demonstrated that *Helicobacter pylori* infection is associated with elevated blood ammonia levels. Inflammatory mediators and cytokines also play important roles along with hyperammonia in the pathogenesis of HE, while recent studies revealed correlations between CRP levels and length of hospital stay. Neuropsychological diagnostic tests, such as Psychometric Hepatic Encephalopathy Score, were especially designed for detecting minimal HE. Imaging investigations, like Computed Tomography or Magnetic Resonance Imaging, show characteristic aspects in advanced stages of liver disease. Recent studies revealed that Mini-Mental State Examination (MMSE) can show significant changes mostly in advanced stages of overt HE, but that it is not an appropriate tool in defining an encephalopathy-related status of patients with cirrhosis. **Keywords**: HEPATIC ENCEPHALOPATHY, LIVER CIRRHOSIS, PATHOGENIC

Cirrhosis represents the end-stage of chronic liver disease from any cause. In the natural history of liver cirrhosis there is a compensated phase (i.e. asymptomatic phase), followed by a decompensated phase, defined by the development of complications, such as portal hypertension and/or liver insufficiency, specifically ascitis, variceal hemorrhage, and/or encephalopathy (1). Hepatic encephalopathy (HE) is a serious complication of liver cirrhosis, negatively affecting both health-related quality of life and survival. Although it is now considered as a continuum of neurocognitive deterioration, HE is usually divided into minimal and overt HE according to mental status change. In minimal HE characteristic are the lack of a detectable brain dysfunction at clinical examination but subclinical psychomotor slowing and cognition deficits are present and clinically relevant. Overt HE is characterized by various symptoms encompassing neuromuscular abnormalities, disorders in intellectual functions, personality and consciousness, traditionally graded in four stages, after West-Haven criteria (2).

PATHOPHYSIOLOGY

HE is a multifactorial syndrome, involving metabolic and biochemical derangements, brain atrophy and edema, impaired cerebral perfusion and hyperpermeability of blood-brain barrier (3). HE occurs in the presence of insufficient hepatic clearance of toxins absorbed from the intestine, resulting in neurochemical abnormalities across the blood-brain barrier.

Specific hypothesis of HE

Ammonia

Cirrhosis represents the final common histological pathway for a wide variety of chronic liver diseases. The blood ammonia levels of cirrhotic patients are usually higher than that of normal people (4).

Ammonia is central in the disease process, contributing to alterations in neurotransmission, oxidative stress, cerebral edema and astrocyte swelling (5). This compound is mainly derived from nitrogenous products in the diet, bacterial metabolism of urea, and deamination of glutamine by the enzyme glutaminase. Ammonia enters the portal circulation from the gut and is converted to urea in the liver. In the presence of significant portosystemic shunting, with or without hepatocellular dysfunction, ammonia concentration rises in blood and crosses the blood-brain barrier. Exposure to increased brain ammonia results in structural alterations in astrocytes that cause swelling and brain edema. Over a long period of exposure to high ammonia levels, astrocytes develop structural changes, known as Alzheimer type II astrocytes (6).

New studies show roles of changes in active glutamine transport in brain edema development during HE. Excessive glutamine (Gln) synthesis in ammonia-overloaded astrocytes contributes to astrocytic swelling and brain edema. Much of the newly formed Gln is believed to enter mitochondria, where it is recycled to ammonia, which causes mitochondrial dysfunction (a “Trojan horse” mode of action). A portion of Gln may increase osmotic pressure in astrocytes and the interstitial space, directly and independently contributing to brain tissue swelling. Accumulation of excess Gln in mitochondria involves a carrier-mediated transport which is activated by ammonia. Excessive synthesis of Gln from ammonia and glutamate catalyzed by an astrocyte-specific enzyme, glutamine synthetase (GS) plays a major role in the pathogenesis of astrocytic swelling (7).

Bowel Bacterial Overgrowth

According to previous studies, the patients with liver cirrhosis have an increase in production and absorption of intestinal bacterial products, which can lead to a continuous flux of lipopolysaccharides and other toxic materials to the portal vein. In the liver, these substances are recognized by Kuppfer cells and thus trigger the release of tumor necrosis factor (TNF), which, together with other products of these cells, leads to hepatocyte lesion (8).

Compounds derived from bacterial activities in the gut can cause neurochemical changes in the brain. These gut-derived toxins (e.g., ammonia, benzodiazepine-like substances) are implicated in the pathophysiology of overt HE. In patients with liver disease or portosystemic shunting, these toxins are inefficiently detoxified, accumulate in the blood, cross the blood-brain barrier, and result in abnormalities, such as altered neurotransmission, astrocyte swelling, and impaired energy metabolism (9).

Helicobacter pylori

Not only bowel bacterial overgrowth must be discussed as an oligosymptomatic

cause of HE, but other bacterial infections in cirrhotic patients might be important, such as *Helicobacter pylori* infection. *H. pylori* infection can produce high blood ammonia concentration in these patients (8).

H. pylori, a bacterium which commonly infects human stomach, has urease activity, which is many times more potent than that of enterobacteria. The *H. pylori* urease in the gastric juice breaks down urea into ammonia and carbon dioxide, and the ammonia is then rapidly absorbed into the blood (4).

From thirteen prospective clinical trials which assessed the effects of H. pylori eradication in patients with liver cirrhosis and HE, seven of these showed a beneficial effect of eradication therapy on minimal HE. All of these studies were highly diverse in design and methodology (10). Eradication therapy in H. pylori-positive cirrhotic patients may have a beneficial influence on hyperammonemia and minimal HE, but evidence from well-designed clinical studies is weak (10).

Inflamation

It is now clearly evident that inflammatory mediators and cytokines play an important role along with hyperammonia in the pathogenesis of HE; possible mechanisms include cytokine-mediated changes in blood-brain barrier permeability, microglial activation, subsequent production of neurosteroids, and altered activity of peripheral benzodiazepine binding sites (6).

Inflammation in the presence of ammonia coactively worsens HE. Inflammation can result from hyperammonemic responses, endotoxemia, innate immune dysfunction or concurrent infection. Treatments currently focus on reducing inflammation and/or blood ammonia levels and provide varying degrees of success (5). It has been shown that the high correlation between CRP levels and the total in-hospital days corroborates the impact of the systemic inflammatory status, not only at the moment of hospital arrival, but also as an indicator of HE regression during the treatment with antibiotics (8). Other studies correlates the CRP levels with encephalopathy occurrence in cirrhotic patients, and many others have described the relevance of inflammation in HE neural physiopathology. These studies demonstrate for the first time that CRP levels are correlated with the hospitalization duration (11, 12, 13). The role of inflammatory cytokines in affecting the blood–brain barrier and increasing the ammonia diffusion in astrocytes was also well described by other authors. In conclusion, CRP reduction must be a clinical target during antibiotic treatment in HE when the values obtained are high (8).

Hyponatremia

In a recently observational study, it has been shown that hyponatremia was a common feature in patients with liver cirrhosis and its severity increased with the severity of liver disease. The existence of serum sodium concentration < 135 mmol/L was associated with greater frequency of HE compared with patients with serum sodium concentration > 135 mmol/L (14).

Other mechanisms for HE

✓ Increased benzodiazepine-like compounds in the brain.

✓ Accumulation of manganese in the basal ganglia: this is implicated in altered dopaminergic neurotransmission and extrapyramidal symptoms.

✓ Alterations in central nervous sys-

tem (CNS) tryptophan metabolites (e.g. serotonin): these changes may underlie some of the classic descriptions of altered sleep-wake cycles seen in early stages of encephalopathy (6).

DIAGNOSTIC OF HE

The diagnosis of HE first requires excluding other potential causes for encephalopathy. Metabolic disorders, infectious diseases, intracranial vascular events, and intracranial space-occupying lesions can present with similar neuropsychiatric symptoms and need to be excluded (15). Consideration of the possibility of HE arises when significant liver dysfunction is known or suspected to be present. Clinical or laboratory evidence of liver failure and/or portal hypertension is usually obvious (6).

The West-Haven grading system (table I), which classifies HE into categories, remains criticized because of its intense subjectivity and low intra- and inter-observer reliability. Therefore, several other more objective diagnostic tools (e.g. neuroimaging, neurophysiological methods or psychomotor tests), were implemented to diagnose both minimal and overt HE, but there is still an ongoing debate which of them should be a diagnostic standard (2).

TABLE I

West Haven criteria for classification of hepatic encephalopathy (6)

Grade	Description	Recommended Tests
0	No abnormality detected	
Covert HE	Normal mental status and neurologic examination Abnormal psychometric tests	>2 SD on 2 or more tests in PHES ICT: >5 lures CFF: cutoff frequency 39 Hz
I	Trivial lack of awareness Euphoria or anxiety Shortened attention span Impairment of addition or subtraction	Naming </= 7 animals in 120 sec Orientation in time and space
II	Lethargy or apathy Disorientation for time Obvious personality change Inappropriate behavior	Disorientation in time (>/=3 items incorrect): ✓ Day of the week ✓ Day of the month ✓ The month ✓ The year Orientation to place
III	Somnolence to semistupor Responsiveness to stimuli Confusion Gross disorientation Bizarre behavior	Disorientation to place (>/=2 items incorrect): ✓ State/country ✓ Region/country ✓ City ✓ Place ✓ Floor/ward Disorientation to time Reduction of Glasgow coma score (8-14)
IV	Coma, inability to test mental state	Unresponsiveness to pain stimuli (Glasgow coma score <8)

CFF, Critical Flicker/Fusion Frequency; HE, hepatic encephalopathy; ICT, Inhibitory Control Test; PHES, Psychometric Hepatic Encephalopathy score; SD, Standard deviation.

1. ***Blood ammonia***. No significant cor-

relation between serum ammonia level and stage of HE has been observed. Most authors agree that measurement of ammonia may be helpful in the initial evaluation of unexplained encephalopathy in patients with not known prior history of liver disease. Normal ammonia values in these patients would argue against a diagnosis of HE (15).

Measurement is not recommended routinely, because it does not change the approach to diagnosis or treatment of patients with suspected HE (6). The measurement of serum ammonia levels for the diagnosis of HE remains controversial: some authorities consider that the use of arterial blood is preferred (15), while others consider that venous ammonia level correlates with the severity of HE as arterial ammonia level does (3).

2. ***Psychometric testing***. Neuropsychological diagnostic tools show a number of practical advantages, making them potent candidates for the common use in HE assessment. Generally, they are simple to perform, not time-consuming and can be used in the outpatient clinic. For this purpose, both single paper-pencil tests (such as the block design test, the trail making test and the digit symbol test), as well as standardized batteries (i.e. the Repeatable Battery for the Assessment of Neuropsychological Status, the Wechsler Adult Intelligence Scale - Revised, the Auditory Verbal Learning, the Everyday Memory Questionnaire) have been implemented. The complex tools have a superior value in comparison to single modalities, because they cover a broad spectrum of neurocognitive deficits. However, among plenty of these tests, only the Psychometric Hepatic Encephalopathy Score (PHES) was especially constructed for detecting minimal HE. Others have a great importance in the diagnostic of cognitive alteration in elderly or neuropsychiatric disorders, in the estimation of the effects of psychoactive drugs or to measure intelligence, while their value in the field of HE remains to be established (2).

Critical Flicker/Fusion Frequency (CFF) test - is based on the hypothesis that retinal gliopathy (hepatic retinopathy) could serve as a marker of cerebral gliopathy in HE. It correlates well with paper and pencil psychometric tests used to diagnose covert HE. It enables discrimination of stage 0 HE from covert HE and overt HE at a cutoff frequency of 39 Hz, with a sensitivity of 55% and a specificity of 100%. It is useful for monitoring fluctuations in the severity of HE in response to precipitating factors or therapeutic interventions (6).

3. ***Electroencephalography (EEG***) - is rarely used clinically, it has some value in research settings (6). It is often performed in patients with their first presentation of HE or in any patient in whom the presentation is atypical in nature. The EEG may have some value in determining the advanced stages of HE, when characteristic triphasic waves are identified (15).

However, the EEG detects cortical neuronal activity and may not reflect a wide variety of neurophysiological events seen in HE . Moreover, it is not broadly implemented in the daily practice, because of its limited availability and the need of experienced personnel to appropriate interpretation of the obtained electroencephalograms (2).

4. ***Computed tomography (for porto-systemic shunts)***

Cirrhotic patients with persistent or recurrent HE commonly have large spontaneous portal-systemic shunts. Using multidetector computed tomography (CT) imag-

ing, it has been shown that large spontaneous porto-systemic shunts are significantly more common in patients with (71%) than without (14%) HE. This approach is ideal in patients with compensated liver disease, where signs and symptoms suggest HE, but the severity of liver disease is mild (15).

5. ***Magnetic resonance imaging (MRI).*** MRI has become a standard technique for the assessment of patients with neurologic manifestations. Patients with liver cirrhosis and no clinical manifestations of HE can have symmetrical high-signal abnormalities in the pallidum on T1-weighted images. Pallidal hyperintensity is not related to the grade of HE; rather, its absence in a patient with cirrhosis and neurologic manifestations suggests an alternative diagnosis. Decreased brain myo-inositol and elevated glutamine by magnetic resonance spectroscopy is characteristic of HE when detected (15).

6. ***Mini-Mental State Examination (MMSE***) is one of the most commonly used methods in the assessment of cognitive mental status. MMSE is one of above mentioned complex neuropsychological tools, that was occasionally used for identification patients with HE in clinical trials and could serve as a potential screening test for this purpose. MMSE assesses cognitive abilities: orientation (spatial and time), attention, concentration, calculation, immediate and short-term memory, visual-spatial orientation, praxis and language skills. Some of these functions are also altered in cirrhotic patients in the course of minimal HE and in stages 1 and 2 overt HE according to West-Haven criteria, long before neurocognitive decline is obvious and clinically easy to detect (2).

In a prospective, quantified electroencephalography study, the authors concluded (2) that MMSE is not an appropriate tool in defining an encephalopathy-related status of patients with cirrhosis and should not be used for this purpose in clinical trials. The authors showed that the score (summary scores and most of the items) is altered in patients with more advanced liver disease measured by Child-Pugh classification and there is a reduction of the most of MMSE items in patients with overt HE, but differences reached the statistical significance only in few items and mostly in more advanced stages of overt HE (i.e. in grade 2 and 3) and the numeric difference between MMSE scores was small and unlikely to be clinically useful.

CONCLUSIONS

Hepatic encephalopathy (HE) is a serious complication of liver cirrhosis, involving metabolic and biochemical derangements, brain atrophy and edema, impaired cerebral perfusion and hyperpermeability of blood-brain barrier. In the pathophysiology of this complication, different hypotheses, including increased blood ammonia levels, increased production and absorption of intestinal bacterial products, *Helicobacter pylori* infection which can produce high blood ammonia levels are discussed. Inflammatory mediators and cytokines also play important roles along with hyperammonia in the pathogenesis of HE, while recent studies revealed correlations between CRP levels and length of hospital stay. Of the diagnostic tools for HE, the measurement of serum ammonia levels remains controversial, because no significant correlation were found between serum ammonia level and HE stage. Of the neuropsychological diagnostic tests, only the Psychometric Hepatic Encephalopathy Score (PHES) was especially designed for

detecting minimal HE. Imaging investigation, such as CT or MRI, show characteristic aspects in advanced stages of liver disease. Also, recent studies revealed that MMSE is not an appropriate tool in defining an encephalopathy-related status, significant changes being found mostly in more advanced stages of overt HE.

In view of the complex aspects in the pathogenesis and diagnosis of HE, there is still a need for developing more specific tests for an objective evaluation of the entire spectrum of this complication, better management and treatment.

PULMONARY REHABILITATION AND QUALITY OF LIFE IN LUNG CANCER PATIENTS (Abstract): Lung cancer is one of the most common types of cancer, often diagnosed in advanced stages. Chest surgery is the main component of curative treatment, the pre-operative functional status being predictive for post-operative morbidity. The potential benefits of pulmonary rehabilitation in lung cancer management appear in pre-operative period, improving the exercise capacity and increasing the number of patients sent to surgery, in post-operative period, decreasing the number of complications, and during the medical treatment of patients with advanced disease, improving the symptoms and increasing the quality of life. The quality of life (QOL) in patients with lung cancer is determined by factors related to patient (stage of disease, co morbidities) as well as treatment (surgery, chemotherapy, radiotherapy). The assessment of QOL is made through questionnaires, mainly related to therapeutic regimens and symptoms. Among the most used are Questionnaire of the European Organization for Research and Treatment of Cancer (EORTC QLQ - C30), Functional Assessment of Cancer Therapy - General (FACT - G), FACT - L (Lung) and the Lung Cancer Symptom Scale (LCSS). **Keywords:** LUNG CANCER, PULMONARY REHABILITATION, QUALITY OF LIFE

Lung cancer is one of the most common types of cancer, with a 5-year survival rate of approximately 15%. Given the long asymptomatic evolution of the lung cancer, in contrast to other tumor types, it is often diagnosed in advanced stages. The main symptoms include cough, hemoptysis, dyspnea, chest pain, weakness, loss of appetite. Therefore, the treatment goals for these patients are relief of symptoms and improving overall survival (1).

The increasing number of alternative lines of therapy and the decreased differences in the clinical effectiveness of drugs improve the survival rate but are often accompanied by severe side effects. In this setting, the importance of estimating the quality of life (QOL) arises although the inclusion of this parameter in lung cancer clinical trials was longtime neglected (1, 2).

Chest surgery is also a main component in the management of patients with lung cancer, the pre-operative functional status being predictive for post-operative morbidity (3). In order to improve it, in recent years appears increasingly more the need for integrate comprehensive pulmonary rehabilitation in clinical approach of the oncologic patient.

THE IMPACT OF PULMONARY REHABILITATION ON THE TREATMENT OF LUNG CANCER

Pulmonary rehabilitation is seen as a comprehensive, non-pharmacological and interdisciplinary patient-centered intervention (4). It targets the impairments derived from chronic pulmonary diseases and its role is well-established and evidence-based in Chronic Obstructive Pulmonary Disease but it began to be adapted to nontraditional areas, such as lung cancer, Chronic Obstructive Pulmonary Disease exacerbations, and critical illness (5).

The potential benefits of pulmonary rehabilitation in lung cancer management appear in three settings, according to Nici and ZuWallack: in pre-operative period, improving the exercise capacity and increasing the number of patients sent to surgery, in post-operative period, decreasing the number of complications and during the medical treatment in patients with advanced disease (tab. I).

TABLE I

The potential benefits of pulmonary rehabilitation in lung cancer

(after Nici and ZuWallack, 2010) (5)

PRE-OPERATIVE
Improves exercise capacity
POST-OPERATIVE
Optimizes airflow
Prevents complications such as hypoxaemia, hypercapnia, respiratory infections
Decreases the number of days with a chest tube
Decreases the length of hospital stay
Pain management
DURING MEDICAL TREATMENT
Improves the symptoms related to chemotherapy/radiotherapy
Increases the quality of life

The official statement of the American Thoracic Society and the European Respiratory Society on pulmonary rehabilitation, released in 2013, clearly states as "noteworthy advances" that pulmonary rehabilitation provided to individuals with lung cancer "has demonstrated improvements in symptoms, exercise tolerance, and quality of life" (6). Emerging data support the usefulness of the multiple interventions included in pulmonary rehabilitation for oncologic patients with lung carcinoma, especially for non-small cell lung cancer (NSCLC).

Surgical resection is an effective curative treatment for lung cancer but low exercise tolerance and multiple serious co morbidities, especially COPD and cardiovascular diseases, limit the access of those patients to surgery. Some small observational

studies concentrated on the impact of short-term pre-operative pulmonary rehabilitation: Bobbio et al. (7) found significantly increased maximal oxygen consumption after 4-week program while Jones et al. (8) obtained significant improvement of maximal oxygen consumption and of six-minute walk test (6-MWT) distance, baseline to pre-surgery, after 5 endurance cycle ergometry session / week. Pre-operative pulmonary rehabilitation seems to be useful even when lung cancer is associated with COPD, a limited number of training sessions leading to shorter length of post-operative hospital stay, fewer days with chest tube and improved lung expansion (9).

Post-operative pulmonary rehabilitation was more extensively studied, even in some randomized controlled trials. Cesario et al. (10) investigated the efficacy of a 4-weeks in-patient respiratory rehabilitation program, after lung resection in patients diagnosed with NSCLC. Several functional parameters – distance achieved at 6-minutes walk test, hemoglobin saturation, dyspnea on Borg scale – were improved after one month versus baseline although the comparison with a group of untreated patients as controls showed no significant difference. A recent 18-months study followed lung cancer patients (n=58) enrolled in a comprehensive rehabilitation program and patients with standard care (n=305): those who had pre-operative rehabilitation had a significant increase of FEV_1 and 6-MWT distance but no effect on post-operative morbidity (11).

Several other researchers also have shown that post-surgery pulmonary rehabilitation interventions improve the peak exercise capacity, walked distance and the main symptoms (dyspnea, fatigue) (12, 13). In terms of quality of life, the reported results are variable (14). A large randomized trial (LUNGEVITY) included 160 patients with histologically confirmed stage I-IIIA NSCLC, after curative-intent lung surgery and randomly assigned them to aerobic training alone, resistance training alone, combined aerobic and resistance training or progressive stretching sessions. This study is ongoing and aimed at identifying the optimal type of exercise training as well as discovering new insight into the physiological effects of such training (15). Glattki and colab. found favorable effects of 6-week multidisciplinary rehabilitation program on 6-MWT distance, FEV_1, FVC, dyspnea on Medical Research Council Scale (MRCS) in patients with lung cancer, both with or without COPD, with or without chest surgery, after completion of treatment (3).

The evidence concerning the role of pulmonary rehabilitation during the medical treatment for lung cancer relies mostly on case series of non-resectable stage III-IV cancer. These patients have a seriously affected quality of life due to severe symptoms such as fatigue, anorexia, dyspnea, pain, depression and anxiety, and also physical deconditioning all that resulting in disability (6). Many of them are unable to perform exercise training but chest physiotherapy and breathing exercise could help controlling the symptoms (16). A recent systematic review (17) evaluated the effect of physical exercise and nutritional interventions in patients with advanced stage NSCLC. The results suggested that exercise and nutrition "may have beneficial effects on unintentional weight loss, physical strength, and functional performance" but these findings were resulted from small studies at significant risk of bias.

There is need for further randomized controlled trials in order to clearly establish

the benefits of pre-operative and post-operative pulmonary rehabilitation, the type of physical training, and the optimal duration of the program in the setting of lung cancer.

NON-SURGICAL TREATMENT IN LUNG CANCER AND QUALITY OF LIFE

During 2001-2011, there were 43 studies conducted to measure health-related quality of life (HRQoL) of patients with lung cancer, 27 having as main objective HRQoL. Most articles illustrated the results of phase III clinical trials: 38 included patients with locally advanced non-small cell lung cancer (NSCLC), especially in stage III/IV, two studies included patients with small cell lung cancer (SCLC) in all stages and three studies included both patients with NSCLC and SCLC. Most studies have investigated the impact of platinum-based drug combinations, 6 studies have investigated the effect of gefitinib and 2 studies concerns of erlotinib(18).

Quality of life (QOL) in patients with lung cancer was assessed by questionnaires, mainly related to therapeutic regimens and symptoms. Among the most used are *Questionnaire of the European Organization for Research and Treatment of Cancer* (EORTC QLQ - C30), *Functional Assessment of Cancer Therapy-General* (FACT - G), FACT-L (*Lung*), *Lung Cancer Symptom Scale* (LCSS), *Hamilton Anxiety and Depression Scale* (HADS), *Brief Pain Index* (BPI).

The most commonly used is the EORTC QLQ-C30; it contains 30 criteria, available in 60 languages (18), while FACT-G questionnaire contains 27 physical, emotional, social, functional elements (19) and FACT-L - 37 items, the last one being suitable for lung cancer (20). Due to inhomogeneity of the patients and treatment regimens, it is difficult to compare the studies on the HRQoL.

However, most researches including comparisons between different chemotherapy regimens did not show significant differences in HRQoL between different treatment arms (21-23). Another group of studies report cautious assumptions of improving HRQoL (24, 25). Only Belani et al. (26) and Reck et al. (27) indicated HRQoL superiority of paclitaxel or docetaxel compared with vincristine or vinorelbine/cisplatin.

Regarding EGFR inhibitors, several authors showed that patients with highly advanced NSCLC treated with gefitinib had improved HRQoL (28) while others correlated that outcome with tumor response (29). Regarding erlotinib, Lilenbaum et al. (30) could not demonstrate significant improvement in progression-free survival, median survival and HRQoL compared to standard chemotherapy regimen but other researchers had positive results in HRQoL when erlotinib is administered in the second line of treatment (31).

LUX- Lung 3 study was conducted on a population of patients with advanced NSCLC and positive EGFR mutation and showed an unprecedented improvement in cancer-related symptoms and quality of life when treated with afatinib, an irreversible inhibitor of the ErbB receptor family as first-line therapy, compared to chemotherapy with pemetrexed and cisplatin, considered the standard of care in this population of patients (32).

Lung cancer or lung metastases often have symptoms for which palliative radiotherapy is effective and improves or maintains quality of life, for about one-third of

the affected patients (33, 34). Many studies assessed at least in one arm the use of palliative thoracic radiotherapy and evaluated QOL or symptoms relief. The researches included patients with NSCLC, with endobronchial brachytherapy alone or in combination with external radiotherapy or evaluated the use of palliative radiotherapy in patients with lung cancer other than NSCLC histological type.

Clinical trials that compared different regimens of palliative radiotherapy fractionation showed improved quality of life and survival in patients with good performance status who received high doses of radiation (TD = 30Gy/10fractions/3Gy/fraction) compared to lower doses (TD = 20Gy/5fractions/4Gy/fraction, 17Gy/2fractions, 10Gy/1fraction), which are mainly used in patients with reduced performance status. This type of radiotherapy could be interspersed between the series of chemotherapy, without causing delay in chemotherapy administration (35-37).

The impact of new radiotherapy techniques (IMRT - intensity modulated radiotherapy, IGRT - guided radiotherapy imaging) and PET - CT imaging integration in the palliative treatment of patients with pulmonary cancer is not clearly defined. Regarding the palliative role of endobronchial brachytherapy, recent analysis of 13 clinical trials concluded that external radiotherapy is superior to endo-bronchial brachytherapy and the addition of the last one has no advantages over external radiotherapy alone (37). So far, it was not demonstrated an advantage of concomitant radio - chemotherapy over sequential administration for symptoms palliation in patients with lung cancer (38).

Irrespective of the chosen therapeutic regimen, there is a great concern for ensuring the best quality of life as possible for the oncologic patients. An interesting study of Gore et al. (39) opposed patients with inoperable lung cancer to those with end-stage chronic obstructive pulmonary disease (COPD) in terms of medical and social care. Patients with COPD had significantly worse activities of daily living (ADL), depression and anxiety status, social functioning than the lung cancer patients and these findings were due to the fact that patients other than oncologic do not receive a holistic care that would include specialized palliative care.

CONCLUSIONS

Patients with lung cancer have a poor prognosis due to their oncologic condition and often to co morbidities. The appropriate selection of therapeutic regimen and inclusion of pulmonary rehabilitation in the management of these patients could lead to improving symptoms, increasing quality of life, less post-operative morbidity or, at least, fit with palliative care, thus helping lung cancer patients to cope with their ruthless disease.

NEWS

OUTBREAK OF EBOLA IN WEST AFRICA

Ebola virus disease is associated with a case fatality rate of 30 to 90%, depending on the virus species. Specific conditions in hospitals and communities in Africa facilitate the spread of the disease from human to human. Three Ebola virus species have caused large outbreaks in sub-Saharan Africa: *ebolavirus*, *Sudan ebolavirus*, and the recently described *Bundibugyo ebolavirus*. Epidemics have occurred in the Democratic Republic of Congo, Sudan, Gabon, Republic of Congo, and Uganda. *Reston ebolavirus* circulates in the Philippines. It has caused disease in non-human primates but not in humans. The fifth species, *Tai Forest ebolavirus*, was documented in a single human infection caused by contact with an infected chimpanzee from the Tai Forest in Ivory Coast. Although this event indicated the presence of *Tai Forest ebolavirus* in West Africa, this subregion was not considered to be an area in which Ebola virus was endemic. New evidence implicates bats as the reservoir hosts for Ebola viruses, though the means of local enzootic maintenance and transmission of the virus within bat population remain unknown. Epizootics caused by Ebola viruses appear sporadically, producing high mortality among non-human primates and duikers and may precede human outbreaks. Epidemics produce acute disease among humans. As of June 10, 2014, the *Guinea* Ministry of Health announced a total of 376 suspect and confirmed cases of Ebola hemorrhagic fever (EHF), including 241 fatal cases, from which 233 cases across Guinea have been confirmed by laboratory testing to be positive for Ebola virus infection. The Ministry of Health and Sanitation of *Sierra Leone* reported 43 laboratory confirmed cases of EHF. An additional 117 suspect cases and 19 fatal cases were also reported in Sierra Leone on June 9. The Ministry of Health and Social Welfare of *Liberia* reported 1 new laboratory confirmed case and one death on June 7, 2014. Genetic analysis of the virus indicates that it is closely related (97% identical) to variants of Ebola virus (species *Zaire ebolavirus*) identified earlier in the Democratic Republic of the Congo and Gabon. MULTIPLE SCLEROSIS AND PREGNANCY (Abstract): Multiple sclerosis is one of the main reasons for invalidation of young adults of both sexes. The disease is more common in women than in men. The illness begins most frequently in patients between the ages of 20 and 40 years, which is also the most fertile period for women. MS is an immune-mediated disease with chronic evolution marked by exacerbations and remissions that amplify the degree of disability. The most common clinical picture is the one with relapse and remission whose evolution is greatly improved after immunomodulatory treatment. We have revised the literature together with the data from the national multiple sclerosis society and the cases that are in the National Programme of Multiple Sclerosis, mainly the ones that are assigned to the regional center of Iaşi, at the Neurology Clinic inside the Clinical Rehabilitation Hospital Iaşi. Pregnancy is quite frequent in female patients with MS. Certain risks are present during pregnancy, birth and breastfeeding and certain protocols must be applied, such as interrupting the immunomodulatory treatment before the conception. Child delivery must be closely monitored and it must take into consideration the dysfunction that the patient has and be adapted to the existing deficits. There are some methods that may be used during delivery for female patients with multiple sclerosis in order to make this process smooth and reduce the risk of postpartum complications. Multiple sclerosis is an invalidating disease, with a high prevalence in women. Pregnancy in patients with MS is not such a natural phenomenon as in a healthy female and it requires a multidisciplinary team in order to ensure the safety of both the mother and the newborn. **Keywords:** MULTIPLE SCLEROSIS, PREGNANCY, BREASTFEEDING, BIRTH.

Multiple sclerosis is one of the main reasons for invalidation of young adults of both sexes. The disease is more common in women reports of 2:1 or even 3:1 being cited. The illness begins most frequently in patients between the ages of 20 and 40 years but can affect also children, adolescents and adults over 50 years (1). The prevalence is 30-150 cases per 100,000 inhabitants and depends on geographic location among others. Multiple sclerosis (MS) is a disease with increasing prevalence in temperate regions and also as we move away north or south of the 45th parallel.

MS is an immune-mediated disease with chronic evolution marked by exacerbations and remissions that amplify the degree of disability. The most common clinical picture is the one with relapse and remission whose evolution is greatly improved after immunomodulatory treatment (2). This form can go into secondary progressive form which requires changing the type of interferon therapy. There are primary progressive forms

which often do not respond to current immunomodulatory treatments. In the last years it was identified the so-called clinically and radiological isolated syndrome that can be treated effectively with some of the known immuno-modulatory therapies (3).

More than half of the female patients with MS are in their fertile period of life which means that while taking the treatment they resort to contraception methods. The efficacy of the disease -modifying therapy has made more and more female patients to want their first child in terms of a significant decrease in the annual rate of relapses and "relapse free" period. At several of the female patients with MS clinical and imaging stabilization was found and approaching or exceeding the age of 30 years has generated a desire for pregnancy which should develop in optimal conditions without adverse effects on the mother or newborn. There are risks related to the possibility of transmitting the disease, worsening health of the mother, the difficulties at birth, during breastfeeding and resumption of immunomodulatory therapy (4).

There were identified multiple genes that may negatively influence the risk of developing the disease in combination with certain environmental factors. Loci have been identified with the help of the major histocompatibility complex (MHC) and seem the most significant encoding IL2R and IL7R. If the mother or father has MS the risk for the children to develop the disease is 3-5 % compared with the general population where the probability is only 0.2 %. If both parents have MS risk increases to 29.5% (5). Among the environmental factors involved temperate climate, exposure to sunlight, disease prevalence in the geographical area of birth etc are involved. In the northern hemisphere the risk of disease is higher in offspring's born in spring compared to those born in winter. The same phenomenon takes place in the southern hemisphere and it is related to sunlight exposure of pregnant patient. Reduction of exposure to sunlight may cause a vitamin D deficiency which would not exert immunomodulatory effect under the influence of the MHC (6).

The health of the mother may suffer some aggravation especially after birth, but therapeutic strategies to prevent and counteract undesirable events exist. We can expect the apparent worsening of preexisting dysfunction or the appearance of new events.

Underlying dysfunction may be of motor type related to sphincters, digestive, sensory, fatigue and seem to be due to the state of pregnancy associated with weight gain. Excess weight can decrease motility already affected by demyelinization more or less extended to some fibers of the cortico -spinal tract. Existing spasticity and ataxic elements may contribute to gait problems.

The presence of demyelinating plaques localized in the spine and the impact of the pregnant uterus on thoraco-abdominal-pelvic cavity can generate or amplify urgency, constipation, mild ventilatory dysfunction. Some sensitive changes related to failure notification to the urinary passage through the urethra, the presence of paresthesia, constrictive or existing areas of hypoesthesia can be easily determined.

Depending on the effort and the temperature of the external environment, the increase in intensity and prolonged daily presence of the fatigue phenomenon can be present. Fatigue has among psychological components also motor ones that exacerbate when the body temperature or of the environment increase or by immersion in hot water. Fatigue can easily change bio-

rhythm prolonging the patients' rest and sleep (7).

The main event announcing the unfavorable evolution both during pregnancy and beyond is the relapse. Although the effect of pregnancy on the evolution of MS is of protective type exacerbations can occur both during pregnancy and after giving birth. PRIMS study says the annual rate of relapse during pregnancy decreases from 0.6 relapses / year before conception to 0.2 relapses /year in the last weeks of gestation. The danger of relapse seems to outline and amplify after birth when the annual rate reaches 1.2 relapses / year interfering with breastfeeding (8).

The occurrence of a relapse during pregnancy requires differentiated treatment depending on the stage of pregnancy. In the first trimester of pregnancy methylprednisolone may not be administered because there were identified cases of children born with malformations of the palate and cataract. Depending on the extent of dysfunction there can be taken into account relapse therapy with methylprednisolone 500-1000 mg/day for 3-5 days in the second and third quarters of the pregnancy. It is known that methylprednisolone can pass through the placenta and can induce preeclampsia, gestational diabetes, venous thrombosis, low birth weight of the child, postpartum adrenal insufficiency. Immunoglobulin (0.2-0.4 g/kg/day, 5 days) seems to be more secure and hassle-free. It is considered as belonging to the same relapse the dysfunction that occur which extend to 30 days after onset. Plasma exchange can be practiced, similarities in the evolution of pregnant patients who have myasthenia (9).

In the first quarter after birth the risk of a new relapse increases, in which case we have to choose between treatment of relapse or discontinuation of breastfeeding. There are therapeutic strategies using bolus methylprednisolone 3-5 days and evacuating the milk secreted after each injection.

The most important moment is the birth itself. The obstetrician and anesthetist must choose the safest solution for the mother and fetus taking into consideration the already existing neurological dysfunctions.

MS does not have any contraindications to vaginal birth or for cesarean. The decision for natural childbirth should take into account maternal age, existing neurological dysfunction at the time, the phenomenon of "fatigue", the fact that the mother is at her first pregnancy or not. The presence of a pyramidal syndrome with paraparesis requires special adaptation with a position in lateral decubitus with the lower limbs supported by a support. Labor and birth in water may be a solution with protective effect by the supporting force and push from the bottom up of the liquid and low body temperature of the pregnant patient in order to prevent fatigue.

Some studies of female patients with MS who gave birth vaginally say that forceps usage was more frequent in comparison with the healthy population. This maneuver would replace the motor and sensitive deficits of the mother with origin in the brain or spinal cord.

Caesarean operation is most commonly practiced type of birth in patients with MS being a deliberate choice that is practiced before the onset of labor in order to avoid possible complications (10).

There are some decisions to make about anesthesia. Most opinions converge towards the use of drugs such as Entonax, Pethidine or TENS machine. There is a preference for epidural anesthesia in comparison with the spinal one. The presemce of the anesthetic in high concentrations in CSF is associated with increased annual

rate of postpartum relapse being suspected a potentiation of low spinal demyelination (11). There were described several cases in which after the anesthesia it was found the so-called autonomous dysreflexia which consists of hypertension spikes, headache, cold sweats and anxiety (12).

Breastfeeding should be encouraged because there is no risk of disease transmission through breast milk. If the mother should receive a drug, it will reach the baby. Planning pregnancy is one of the important moments in the life of female patients with MS. There is some risk of disease worsening if the immuno-modulatory treatment is stopped for at least 15 months. In the first three months the birth control and immunomodulatory drugs should be stopped. For patients treated with glatiramer acetat only two months of interruption should be enough. At least three months after stopping natalizumab should the conception process begin. Fingolimod requires only two months distance to conceive from the moment of interuption. Special measures should be taken for patients who were treated with combined drugs or only with mitoxantrone. The aggressiveness of this product and its teratogenic impact requires initial contraceptive therapy 6 months after stopping administration (13).

Fertility in female patients with MS is under the influence of contraceptive medication and the modifying disease treatment. Interrupting them is the first step towards planning pregnancy. There are no reliable data on negative influence of immunomodulatory medication on fertility, the increased risk of miscarriage in patients undergoing treatment with interferon beta being cited. Animal studies have shown reduced fertility after treatment with Natalizumab, a phenomenon that is not met by the use of fingolimod. Mitoxantrone has negative effects on fertility which means stopping it long before conception. Reduced effect of contraceptives may be induced by concomitant administration of drugs such as Modafinil, Phenitoin and Carbamazepine. Mitoxantrone or cyclo-phosphamide medications may exert negative influences on spermatozoons and oocytes.

Spontaneous fertility appears to be influenced in MS patients in which the effect of the medication is combined with some couple problems. Sexual dysfunction is a consequence of erection problems, motor deficit, sensory deficit, sphincter deficit or psychological issues. Decreased libido is a phenomenon that applies to both sexes and reduced testosterone in male patients will affect fertility. To counter some of the aspects of the disease and the treatment some methods such as in vitro fertilization may be used. The risk is to increase the annual rate of relapses. Cryostorage or egg cryopreservation followed by selfgrafting may be another solution (14).

Fertility in men appears not to be negatively affected; the recommendations are between continuing the treatment and discontinuation for some time before conception.

Our experience covers a total of 450 patients of whom more than half are women. Most of the female population is at fertility age (18-40 years).

A significant number of patients had one or more children before being diagnosed with MS and treated. After starting treatment more patients expressed a desire to have children. Our recommendations supported starting immunomodulatory treatment and follow-up to stabilize the evolution of the disease. This stabilization occurred after a minimum of 3 years and maximum of 5 years. At this time some patients have given up the desire to have

off springs because of the disease. Until now they were born 28 healthy children of whom a pair of twins. Our patients had no relapse during pregnancy or breastfeeding. They restarted immunomodulatory treatment within four months after birth.

The EDSS (disability score) of the female patients who gave birth was 1.5. The largest EDSS was 4.5 in a person aged 33 years old with 9 years of disease with initial treatment with glatiramer acetate and after birth being switched to interferon beta. At this moment she continues with interferon beta. We have treated a person who has made a second child under treatment with interferon beta. The average age of those who gave birth was 30 years.

CONCLUSION

Multiple sclerosis is an invalidating disease, with a high prevalence in women. Pregnancy in patients with MS is not such a natural phenomenon as in a healthy female and it requires a multidisciplinary team in order to ensure the safety of both the mother and the newborn. More studies are needed in order to have a specific protocol in the future.

THE IMPACT OF RESPIRATORY TRACT INFECTIONS ON THE NUTRITIONAL STATE OF CHILDREN WITH CYSTIC FIBROSIS (Abstract): Cystic fibrosis (CF) is a life-shortening, autosomal-recessive disorder characterized by intestinal malabsorption, impaired growth and lung disease. Recurrent pulmonary infections in children with CF are often associated with nutritional deficiencies. **Aim:** To emphasize the effects of recurrent pulmonary infections on nutritional status in children with CF. **Material and methods**: This retrospective study included 27 patients diagnosed with CF between 1994 and 2011 in the 3rd Pediatric Clinic of the Iasi "Saint Mary" Children's Hospital. The nutritional status was assessed according to ponderal index (PI), body mass index (BMI), Z score for weight and waist. Correlations between the age of onset of symptoms, age at diagnosis, and frequency of infectious episodes, identified bacterial agents and nutritional status were established. **Results:** Patients aged between 3 months old and 17 years old with an average of 49.48 months ± 9.83DS; sex ratio was 1.7:1. The patients were diagnosed late, one month to 112 months (average 41.11 months±9.4DS) from the first symptoms until the moment of diagnosis. The clinical forms of CF in the study group were: predominantly respiratory manifestations in 48.14% of cases, and the mixed type, with both respiratory and digestive symptoms, in 18.52% of cases. Delayed weight and/or height gains were identified in 85.19% of cases. The etiologic agents involved in pulmonary infections were *Staphylococus aureus* (48.14%), *Pseudomonas aeruginosa* (33.33%), *Stenotrophomonas maltophilia* (18.51%), *Haemophilus influenzae* (14.8%), *Klebsiella pneumoniae* (11.10%), *Moraxella catarrhalis* (7,40%), *Streptococcus pneumoniae* (7.40%), *Neisseria sica* (7.40%). Pulmonary infections caused by *Staphylococus aureus, Pseudomonas aeruginosa*, and *Stenotrophomonas maltophilia* were more often associated with nutritional status abnormalities. **Conclusions:** In small children with CF pulmonary infections due to various causative agents cause a slow rate of growth (both weight and height). Good nutrition and adequate early treatment of pulmonary infections are beneficial for the general state of affected children and are very important in maintaining their health. **Keywords:** CYSTIC FIBROSIS, CHILDREN, MALNUTRITION, PULMONARY INFECTION.

Cystic fibrosis (CF) is a life-shortening, autosomal-recessive disorder that is characterized by intestinal malabsorption, impaired growth, and lung disease (1). Opti-

mal nutritional status is vital in children with CF to enhance their quality of life and prognosis (2, 3). Despite the hyper caloric diet, some children do not achieve the length and weight growth standards. Pulmonary recurrent infections in CF children are often associated with nutritional deficiencies.

MATERIAL AND METHODS

We conducted a retrospective study based on medical observation sheets that included 27 patients diagnosed with CF between 1994 and 2011 in the 3rd Pediatric Clinic of the Iasi "Saint Mary" Children's Hospital. Nutritional status was assessed according to ponderal index (PI), body mass index (BMI), Z score for weight and waist. In patients with pulmonary disease the micro bacteriological exam of hypopharyngeal aspiration was performed. In these patients, we established correlations between the ages of onset of symptoms, age at diagnosis, frequency of infectious episodes, identified bacterial agents, and nutritional status. Statistical data analysis was performed using *SPSS 19.0*. The error of statistical estimations was of 5%, corresponding to a 95% confidence interval.

RESULTS

Patients aged between 3 months old and 17 years old with an average of 49.48 months ±9.83 SD (mean age 4.1 years). Sex distribution showed that 17 patients were male (62.96%) and 10 females (37.04%), sex ratio: 1.7: 1.

Although the onset of disease was recorded in the first year of life in 77.77% of cases, the CF diagnosis was made in 70.37% of cases after the first year of life. So, without newborn screening for identification of CF, the patients were diagnosed late, after an average 41.11 months±9.4 SD (ranges one month to 112 months) from the time of the first symptoms until the moment of diagnosis.

The average age at the onset of the disease was 7.23 months±4.32 SD, ranging between 1 day and 13 months. The disease had an early onset, during the first 3 months of life, in 22.22% of cases.

The clinical forms of CF in the study group were: predominantly respiratory manifestations in 48.14% of cases, predominantly digestive symptoms in 33.33% of cases and the mixed type, with both respiratory and digestive symptoms, in 18.52% of cases.

The respiratory disease started in 25.9% of cases with bronchopneumonia and in 18.5% of cases with recurrent wheezing and chronic cough (fig. 1).

In patients with the mixed type of disease, we found that severe exocrine pancreatic failure associated with recurrent respiratory infections lead to severe forms of CF. Analyzing the relationship between the age of onset and the severity of pancreatic and respiratory failure, we found that an early onset is extremely often associated with severe forms of disease (r=0.696, p=0.418, 95% CI) (fig. 2).

Of the 27 patients, only 14.81% (4 patients) had normal weight. Delayed weight and/or height gains were found in 85.19% (23 patients) of cases, with various stages of low body weight according to Z score: 37.04% of cases (10 patients) – stage I dystrophy, 18.52% (5 patients) – stage II dystrophy, 7.41% (2 patients) - stage III dystrophy (fig. 3).

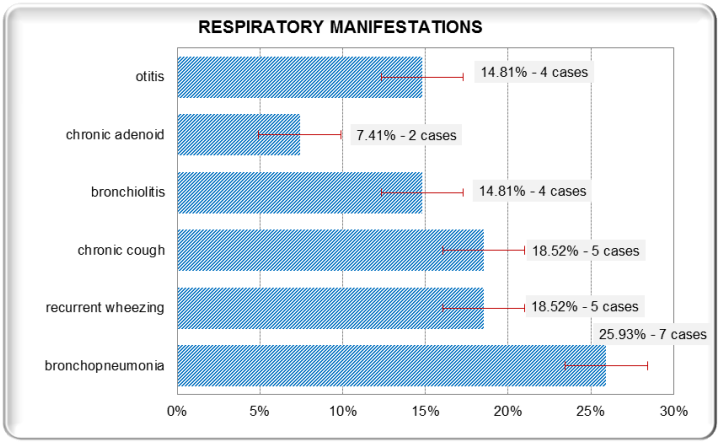

Fig. 1. Respiratory manifestation in children with CF

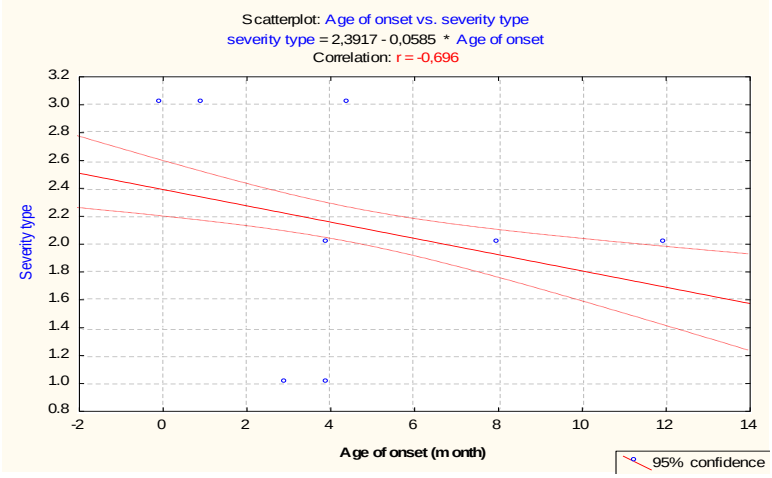

Fig. 2. Correlation between the age at onset and disease severity

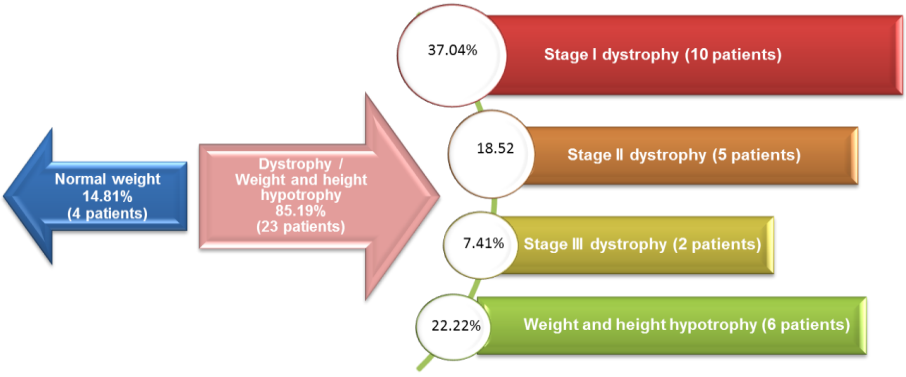

Fig. 3. Nutritional status in patients with CF

In the study series, we noticed that an early onset and recurrent pulmonary infections are highly related to an abnormal nutritional state, as demonstrated by multivariate analysis. Partial correlations from multivariate analysis between the age of onset, presence of recurrent infections (r=–0.434, p=0.0045), and nutritional state abnormalities (r=–0.517, p<<0.05) were statistically significant.

TABLE I
Multiple correlation of disease onset vs. impaired nutritional status and recurrent infections

Multiple correlation	**Estimated value**
Coefficient of multiple correlation	0.88694
Multiple R^2	0.78667
F	44.24963
p (95%CI)	0.00000
Std. Err. of Estimate	2.07712

Partial correlation disease onset *vs.*	**Correlation Coefficient (Beta)**	**Std.Err. (Beta)**	**B**	**Std.Err. B**	**t**	**p-*95% confidence interval***

Recurrent infections	-0.434356	0.13877	-3.9066	1.24819	-3.129	0.004549
Impaired nutritional status	-0.517684	0.13877	-4.3928	1.17761	-3.730	0.001039

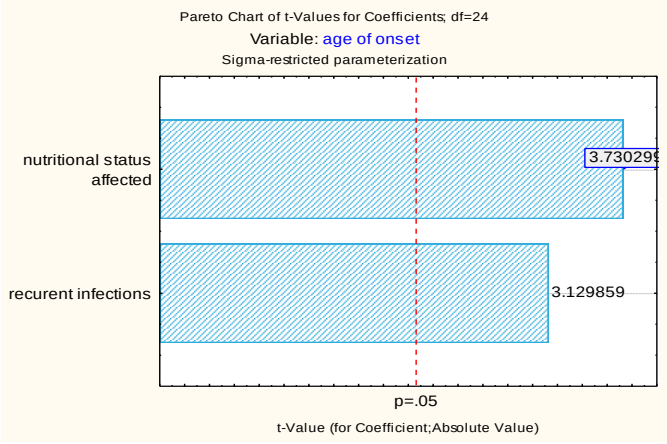

Fig. 4. Absolute value of statistics "t" in the evaluation of multivariate analysis (onset *vs.* impaired nutritional status, recurrent infections)

For the multivariate analysis of the implications of onset time in recurrent infections (nutritional state abnormalities) we applied logistic regression. Table I shows the predictive factors for recurrent infections incidence and nutritional state abnormalities.

The results prove that early onset determines both the occurrence of recurrent infections (b=-0.434-partial correlation indices) and nutritional state abnormalities (b=-0.517) (tab. II).

The causative agents of pulmonary infec-

tions were *Staphylococus aureus* (*S. aureus*) (48.14%), *Pseudomonas aeruginosa* (*Ps. aeruginosa*) (33.33%), *Stenotrophomonas maltophilia* (18.51%), *Haemophilus influenzae* (14.8%), *Klebsiella pneumoniae* (11.10%), *Moraxella catarrhalis* (7.40%), *Streptococcus pneumoniae* (7.40%), *Neisseria sica* (7.40%) (fig. 5).

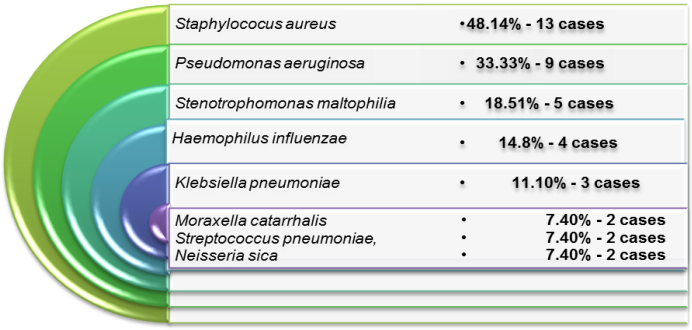

Fig. 5. Etiologic spectrum of respiratory infections

Pulmonary infections due to *S. aureus*, *Ps. aeruginosa* and *Stenotrophomonas maltophilia* were more often associated with nutritional status abnormalities.

DISCUSSION

In children, multiple diseases, CF included, are associated with weight and growth deficit. In the absence of neonatal screening, in 88.88% of cases the disease was diagnosed late, the average age at the time of diagnosis being 3.4 years old compared with a mean age of onset of symptoms of 7 months old. The clinical forms with pulmonary manifestations were the most common in children with CF, the clinical form with predominantly respiratory symptoms being found in 48.14% of cases, and the mixed forms, respiratory and digestive, in 18.52% of cases. In all 5 patients with respiratory and digestive forms, the association between exocrine pancreatic failure and recurrent respiratory infections caused severe disease progression.

Impaired growth (weight and/or height) was found in 23 patients (85.19% of cases). In this study group, the onset at a young age and repeated respiratory infections were correlated significantly (r = 0.94, CI = 95%) with impaired nutritional status. Staturo-ponderal hypotrophy (SPH) was identified in 6 patients with chronic lung infections: three patients with methicillin-resistant *S. aureus* (MRSA), one patient with *Ps. aeruginosa* and two patients MRSA and *Ps.aeruginosa* co-infection. Of the six pa-

tients with SPH, two children were diagnosed late, at the age of ten and eight, respectively. So, the earlier onset and the late diagnosis were associated with many respiratory infections and poor nutritional status. The main pathogen of CF lung infections is *S. aureus* (3, 4, 5, 6). The study by Beringer et al. found that about 50% of children with CF until the age of 10 had chronic pulmonary infections with *S. aureus* (7). Miall et al. compared 10 children with CF and MRSA versus 18 patients with CF negative for MRSA; they found deteriorations in height, weight, and BMI in the MRSA positive group, but only the change in height was statistically significant ($p = 0.039$) (8).

In patients with CF, *S. aureus* itself is not a common cause of morbidity and mortality, but because of the progressive destruction of lung tissue and worsening pulmonary obstruction, it favors co-infection with *Ps. aeruginosa* (8, 9, 10, 11). In our study, pulmonary infections with *S. aureus*, *Ps.aeruginosa* and *Stenotrophomonas maltophilia* were more often associated with poor nutritional status.

Despite adequate pancreatic enzyme replacement therapy and nutritional supplements, the weight and height gains were not satisfactory due to loss of appetite and frequency of catabolic stress during pulmonary exacerbations, requiring repeated hospitalizations. Recurrent respiratory infections, inappropriate nutritional intake and low compliance to substitution treatment caused altered nutritional status. The increased incidence of respiratory infections at a small age is associated with an abnormal nutritional status in CF children. On the other hand, nutritional status has a significant effect on pulmonary disease progression and survival in patients with CF (12, 13).

CONCLUSIONS

All patients presented delayed growth (both weight and height), CF onset at a young age and repeated lung infections. All patients with pulmonary infections caused by *S. aureus* (48.14% of cases) and *Ps. aeruginosa* (33.33% of cases) had a poor nutritional status. Newborn screening is essential for diagnosing CF and thus for preventing airway colonization by aggressive germs and so is the early initiation of an adequate nutritional management.

FACTORS RESPONSIBLE FOR RELATIVE POSITION OF INTERPROXIMAL PAPILLA IN HEALTHY SUBJECTS

A group of Korean researchers conducted a study that examined the factors that can be associated with the appearance of the interproximal papilla.Were examined one hundred and forty-seven healthy interproximal papillae between the maxillary central incisors (male, 74; female, 73; average age, 25.36±7.58 years). A digital photograph and periapical radiograph of the interdental embrasure were taken for each subject using a 1-mm grid metal piece. The recorded parameters were: the amount of recession of the interproximal papilla, contact point-bone crest distance, contact point-cemento-enamel junction distance, cemento-enamel junction-bone crest distance, inter-radicular distance, tooth shape, embrasure space size, interproximal contact area, gingival biotype, papilla height, and papilla tip form. The amount of recession of the interproximal papilla was associated with: 1) increase in contact point-bone crest, contact point- cemento-enamel junction, and cemento-enamel junction -bone crest distance; 2) increase in the inter-radicular distance; 3) triangular tooth shape; 4) decrease in the interproximal contact area length; 5) increase in the embrasure space size; 6) flat papilla tip form. The amount of gingival recession was not associated with the gingival biotype or papilla height. In the triangular tooth shape, the contact point-bone crest distance and inter-radicular distance were longer, the interproximal contact area length was shorter, and the embrasure space size was larger. The papilla tip form became flatter with increasing inter-radicular distance and cemento-enamel junction-bone crest distance. The relative position of the interproximal papilla in healthy subjects was associated with the multiple factors and each factor was related to the others. A triangular tooth shape carries a higher risk of recession of the interproximal papilla because the proximal contact point is positioned more incisally and the bone crest is positioned more apically. This results in an increase in recession of the interproximal papilla and flat papilla tip form. (Kim JH, Cho YJ, Lee JY, Kim SJ, Choi JI. An analysis on the factors responsible for relative position of interproximal papilla in healthy subjects. *J Periodontal Implant Sci*, 2013; 43 (4): 160-167)

CORRELATIONS BETWEEN STATE ANXIETY AND QUALITY OF LIFE IN METASTATIC BREAST CANCER PATIENTS (Abstract) **Aim:** to evaluate the correlations between perceived state anxiety during chemotherapy and quality of life in metastatic breast cancer patients. **Material and methods**: 62 metastatic breast cancer patients were evaluated during chemotherapy concerning age, living environment, marital status, social support and preexisting financial difficulties, the histological type of cancer, the site of the metastasis, the time from diagnosis, the type of surgical intervention, dexamethasone use, somatic comorbidities and the radiotherapy. The STAI-X1, BDI- IIA and the QLQ 30 (Quality of Life Questionnaire 30) plus BR 23 (Breast 23) questionnaires were applied. For the statistical analysis we used the *SPSS 13* package. **Results:** 24 subjects were experiencing low state anxiety (≤39), whilst 38 had significant state anxiety (>39). Statistically significant differences were encountered between the two compared subgroups concerning the living environment, the type of surgical intervention, the marital status, the social support and the mean BDI scores, adjusted means were calculated for the items considered to potentially influence quality of life. Social, emotional and role functioning had lower scores in the low state anxiety group. Fatigue, future perspective, chemotherapy induced side effects, breast symptoms, upset by hair loss and sexual functioning were more disturbing in the high state anxiety group. The general health/quality of life mean score was lower in the low state anxiety group. **Conclusions**: Higher state anxiety correlates with certain quality of life items, suggesting that psychological counselling and appropriate therapy induced side effects management should be a priority in the palliative care for metastatic breast cancer patients.
Keywords*:* CANCER, BREAST, ANXIETY, QUALITY OF LIFE, PAIN.

Breast cancer is the most frequently encountered form of malignancy in women and it represents around 28% of the reported cancers in Europe (1). The National Cancer Institute estimates that 12.7% of women born today will be diagnosed with breast cancer during their lifetime (2). In Romania over 6000 new cases, usually in an advanced stage, are diagnosed every year, with an incidence of 56.84/100000 and a reported mortality of 39.28/100000. A recent study of the International Agency for Cancer, published in 2010 in the British Medical Journal, describes an increase with 17% of the mortality generated by breast cancer in Romania in the last few years, most probable due to the dysfunctional strategies of early detection and treatment

(3). Cancer signifies a serious threat on someone's existence and there are studies that evaluate over 77% of the subjects having this diagnosis as experiencing anxiety symptoms generated by the disorder itself or by its therapy (4). In 2005, Burgess et al. described a decreasing annual prevalence of depression and anxiety of 50% in the first year, 25% in the second, third and fourth year and 15 % in the fifth year after being diagnosed with breast cancer (5).

Anxiety in cancer is a sensitive issue, generating relational problems with both medical staff and caregivers. Its prevalence at a psychopathological level is reported to be 10-30% (6). Moreover, its relation with quality of life is complex and bivariate. Although anxiety disorders are correlated with deficits in the quality of life, there are studies that postulate that their impact is not a significant one (7). Nevertheless, state anxiety was considered to be a risk factor for chemotherapy induced nausea and vomiting (8). In 2004, Schreier et al. found a negative correlation between state and trait anxiety scores and quality of life in a sample of 48 women receiving chemotherapy for breast cancer (9). It is of great interest to determine the causing factors and the specificity of anxiety in oncology, and its correlation with quality of life items, in order to have a better management of complex situations, leading to best palliative care.

MATERIAL AND METHODS

We conducted a clinical study at the Oncological Institute "Ioan Chiricuță" Cluj-Napoca, starting from January 2011 until November 2012, on a group of 62 women, aged over 18, suffering from metastatic breast cancer, evaluated in the day care hospital. All of the subjects were undergoing chemotherapy at the moment of the evaluation. The exclusion criteria were brain metastasis, psychiatric history, psychotropic medication administration (current or within the last 6 months), alcohol or illicit substances abuse/ addiction, confusion, unable or unwilling to sign the written consent, patients taking psychoactive medications, others than chemotherapy and premedication for chemotherapy. The STAI-X1, BDI-IIA and the EORTC QLQ 30 (Quality of Life Questionnaire 30) plus BR 23 (Breast 23) questionnaires were applied. The evaluated items were the age, the living environment, the marital status, the social support and pre-existing financial difficulties, the histological type of cancer, the site of the metastasis, the time from the announcement of the diagnosis, the type of surgical intervention, the use of dexamethasone as premedication, the somatic co morbidities and the radiotherapy. A cut off value of 39 was established for STAI-X1 scores, splitting the group into clinically significant state anxiety (>39) and low state anxiety (≤39). The two resulting groups were compared regarding the quality of life items. For the statistical analysis we used the *SPSS 13* package, including the T Student test. The distribution of the variables was tested with Skewnes and Kurtosis, and the general data were analyzed with the Chi Square test.

The study was approved by the medical ethics commission of the University of Medicine and Pharmacy "Iuliu Haţieganu" Cluj-Napoca.

RESULTS

The age mean in the group was 54.37 years old, with a minimum of 30 and a maximum of 81. The majority lived in the urban area (79%), were married (77.4%) and bene-

fited from a strong social support (91.9%). Approximately half of the group reported important financial difficulties (51,6%). According to the TNM staging system, all patients were in the IVth stage evolution of the disease. Most of the subject had bone metastasis (51.61%). From the histological perspective, as expected, the majority (85.5%) were infiltrating ductal carcinomas, followed by the infiltrating lobular carcinomas (7.14%), the intraductal (3.2%) and the undifferentiated types (3.2%) and in a smaller percent we discovered lobular pleomorphic (1.6%) and medullar carcinomas (1.6%). A number of 34 patients had a history of unilateral breast mastectomy, 19 of them breast-conserving surgery, whilst 9 were considered to be inoperable. 48.4% underwent radiotherapy (tab. I).

Most of the participants were not suffering from other somatic illnesses (40 cases), part of them having however co morbidities (hypertension, diabetes mellitus, gastritis, goitre, anaemia, leyomioma, spondylitis, deep vein thrombosis).

According to the STAI X1 scores, 24 subjects (38.70%) were experiencing low state anxiety (≤39), whilst 38 of them (61.29%) had significant state anxiety (>39) (tab. II).

TABLE I

Previous therapies

	Yes(number)	No (number)	Yes (percent)	No (percent)
radiotherapy	30	32	48.4%	51.6%

TABLE II

BDI IIA scores

	STAI X1	N	Mean	Standard deviation
BDI	<= 39	24	11.0417	7.77666
BDI	>39	38	19.2895	8.47224

Statistically significant differences were encountered between the two compared subgroups (the low state anxiety and the high state anxiety one) concerning the living environment ($p<0.0001$), the type of surgical intervention ($p=0.010$), the marital status ($p=0.0001$), the social support ($p<0.0001$) and mean BDI scores.

Previously published research report showed that living environment (10), marital status (11) and depressive symptoms (12) have an influence on the quality of life. Moreover, the type of surgical treatment (breast-conserving versus mastectomy) (13), and the subject's perceived social support (14) also were proved to impact on the quality of life. In consequence, we used the general linear model in order to adjust the means of quality of life questionnaire for those items. After these corrections significant variations were observed for certain quality of life items between the two subgroups (tab. III).

The functional scales mean scores were significantly higher in subjects with low state anxiety.

Concerning the QLQ 30 symptom scales, the only item having a higher ad-

justed mean score in the higher state anxiety group was fatigue. The adjusted mean score for diarrhoea did not register a normal distribution.

Evaluating specific breast cancer items by QLQ 30 BR 23, significant variations were documented for future perspective; chemotherapy induced side effects, breast symptoms, upset by hair loss and sexual functioning, with higher mean scores for subjects with state anxiety over the cut off score of 39 points in STAI X1. The adjusted mean score for sexual functioning did not register a normal distribution (tab. IV).

TABLE III
Functional scales

	STAI X1	N	MEAN	Standard deviation	p
Prediction value for role functioning	≤ 39	24	48.3890	19.43992	0.0290
	≥40	38	35.6617	23.08044	
Prediction value for emotional functioning	≤ 39	24	74.9347	69.5731	0.0160
	≥40	38	56.4796	56.9373	
Prediction value for social functioning	≤ 39	24	69.4036	21.47722	0.0360
	≥40	38	59.0151	21.47474	

TABLE IV
Specific subscales

	STAI X1	N	Mean	p
Prediction value for future perspective	≤ 39	24	46.5890	0.013
	≥40	38	28.0632	
Prediction value for side effects	≤39	23	32.2360	0.016
	≥40	38	42.1011	
Prediction value for breast symptoms	≤39	24	16.2071	0.016
	≥40	38	25.5781	
Prediction value for upset by hair loss	≤39	16	32.9202	0.015
	≥40	26	54.0972	
Prediction value for sexual functioning	≤39		11.2968	0.004
	≥40		4.3518	

QLQ/ General health mean score was higher in the low state anxiety subgroup (p=0.011).

DISCUSSION

The STAI Y inventory is one of the most frequently administered anxiety self-report scales, especially in somatic co morbidities (16). The decision to only use the STAI X1 questionnaire was driven by the aim of the study, specifically the evaluation of state anxiety experienced in the context of both cancer diagnosis and outpatient chemotherapy. The statistical analysis of our data resulted in interesting results concerning the quality of life subscales, evaluated by the EORTC QLQ 30 and BR 23 questionnaire (17).

Regarding the functional scales, those refer to the last week in subject's life. Pa-

tients with dysfunctional role and social status were encountered in the higher state anxiety group, which is suggestive for a lower frustration tolerance and certain dysfunctional copying mechanisms involved in their adjustment to the somatic disorder. The differences in the emotional functioning mean scores are not surprising, considering the fact that they go along with STAI X1 evaluating the same issue.

Cancer treatment–related fatigue is categorized as chronic fatigue because it is present over a long period of time, interferes with functioning, and is not completely relieved by sleep and rest (15) and it is an important symptom to target in the treatment of cancer survivors (16). It is well recognized to generate depression and anxiety, and in our study it correlated with higher levels of state anxiety. Higher scores for chemotherapy side effects, breast symptoms and upset by hair loss were found in the high state anxiety group, suggesting that cancer therapies are perceived as aggressive and stressful.

The last months of sexual life was evaluated by BR 23 questionnaire. The results of our study suggest that dysfunctional sex life generated higher state anxiety during chemotherapy. Still, the relationship could be bivariate, as anxiety is known to be detrimental to sexual life (17). A pessimistic future perspective also generates a higher state anxiety during chemotherapy.

The limits of the study consist in the relatively small sample of evaluated subjects and in disregarding the trait anxiety of the subjects.

CONCLUSIONS

Higher state anxiety correlates with certain quality of life items, suggesting that psychological counselling and management of side effects induced by appropriate therapy should be a priority in the palliative care for metastatic breast cancer patients.

AKNOWLEDGEMENTS

The statistical analysis of the sample was performed by Md PhD Adriana Rusu.

No conflict of interests.

PARKIN PROTEIN - THE LINK BETWEEN TUBERCULOSIS AND PARKINSON'S DISEASE

Tuberculosis (TB) is a major public health problem worldwide through incidence and mortality. Parkinson's disease is a common neurodegenerative disorder that affects million people. The pathogenesis of TB is the result of interaction between foreign bacteria and the immune response of the host organism. In macrophages, mycobacteria are surrounded by a chain of ubiquitin protein that promotes bacterial destruction (xenophagy). The mitochondrial dysfunction has a causal role in Parkinson's disease pathogenesis. The malfunction mitochondria are disposed by autophagy. According to Cox and colleagues, the Parkin protein is a ubiquitin ligase that has an important role in ubiquitin-mediated xenophagy of mycobacteria and also in autophagy. They showed that Parkin gene polymorphisms that induce a Parkin protein deficit, increase susceptibility to bacterial infection with intracellular pathogens (*Mycobacterium tuberculosis*, *M. leprae* and *Salmonella enterica* serovar Typhi). Also, mutations in the Parkin gene increased susceptibility to Parkinson's disease. The malfunction of this protein is associated with a loss of nerve cells. The finding suggests that Parkin protein could be a target for new drugs from fight with tuberculosis infection. (Manzanillo PS, Ayres JS, Watson RO, Collins AC, Souza G, Rae CS et al. The ubiquitin ligase parkin mediates resistance to intracellular pathogens. *Nature*, 2013; DOI: 10.1038/nature12566).

2. Discipline of Parasitology
Clinical Hospital of Rehabilitation Iasi

INFLUENCE OF METABOLIC SYNDROME PROFILE ON CARDIOVASCULAR RISK (Abstract): **Aim:** The trial was conducted on patients with metabolic syndrome hospitalized between 01.01.2012-31.12.2012 at Cardiovascular Rehabilitation Clinic of the Rehabilitation Hospital Iasi. **Material and methods:** Patients included in the study were analyzed according to age and sex, criteria for the clinical definition of the metabolic syndrome, known cardiovascular diseases, diabetes mellitus type 2 or type 1. **Results:** Metabolic syndrome components analysis showed statistical differences between the sexes, in case of certain cardiovascular risk factors. The frequency of cardiovascular risk factors (obesity, hypertriglyceridemia, hypertension, glycemic profile modification) was higher among women, the only risk factor most common in males was the decrease of HDL cholesterol. The statistically significant difference occurs in hypertriglyceridemia ($p = 0.001$) and HDL-Cholesterol ($p = 0.000$). Patients included in the study were studied depending on the frequency of the main cardiovascular diseases, secondary to the metabolic syndrome: ischemic heart disease, stroke, peripheral arterial disease of the lower extremities. **Conclusions:** Association of impaired glucose tolerance/diabetes mellitus, arterial hypertension and hypertriglyceridemia recorded an additional risk of developing CIC or ischemic stroke, independent of sex. **Keywords**: OBESITY, HYPERTRIGLYCERIDEMIA, HYPERTENSION, CARDIOVASCULAR RISK.

The metabolic syndrome (MS) is a more and more debated research objective, as its clinical and biological components: obesity, insulin resistance, impaired glucose tolerance or diabetes, hypertension and dyslipidemia, gives individuals an increased cardiovascular risk (1). Current studies have shown that metabolic syndrome increases the risk of adverse cardiovascular events (2) accelerates the age-related changes in blood pressure, both in the carotid arteries and in large arteries, similar in both sexes (4).

MATERIAL AND METHODS

The trial was conducted on patients with metabolic syndrome hospitalized between 01.01.2012-31.12.2012 at Cardiovascular Rehabilitation Clinic of the Rehabilitation Hospital Iasi.

The inclusion criterion was the presence of increased cardiovascular risk, defined according to the European Society of Car-

diology guidelines (5). Patients included in the study were analyzed according to:

- epidemiological data - age and sex;
- criteria for the clinical definition of metabolic syndrome (MS);
- known cardiovascular disease, diabetes mellitus type 2 or type 1.

Centralization of data was done in a nominal and numerical form. Statistical comparison of groups was performed according to the type of data, size of groups, the distribution of variables using Fisher's exact test, Shapiro-Wilk test, Mann-Whitney U test and ANOVA. Statistical analysis was performed with *SPSS Statistics 17.0* and *Microsoft Office Excel* 2007.

RESULTS AND DISCUSSION

1. Epidemiological data

We included 336 patients with a mean age of 62.7 years and age limits between 34 and 89 years. The analysis by sex targeted a total of 188 women (56%) and 148 men (44%) (fig. 1).

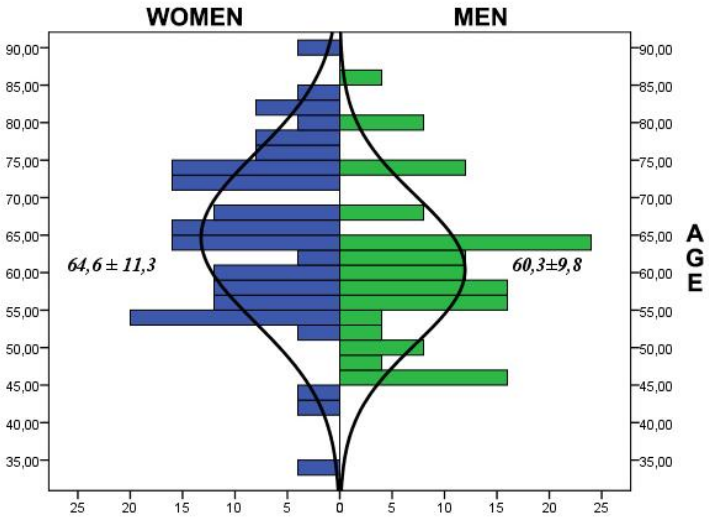

Fig. 1. Distribution of patients according to age, sex

2. Metabolic syndrome

Abdominal obesity

Abdominal obesity was present in 152 patients (45.2%), of whom 64 were men (42.1%) and 88 women (57.9%). By using Fisher's exact test (Exact Sig. (2-sided)) we obtained a p=0.294 (at a significance level of 0.05), concluding that there is no statistical difference between the sexes in terms of the presence of abdominal obesity.

Hypertriglyceridemia

Hypertriglyceridemia was present in 284 patients (84.5%), of which 120 were men (42.2%) and 164 women (37.8%). In the working group the median triglyceride value was 129.5 mg / dl higher among women (141 mg / dl) than among men (122 mg / dl) (fig. 2).

The analysis of triglycerides values corresponding to the two sexes showed that the data distribution is not comparable (ANOVA p = 0.162). *So*, there was no significant difference between triglycerides value according to sex (fig. 3).

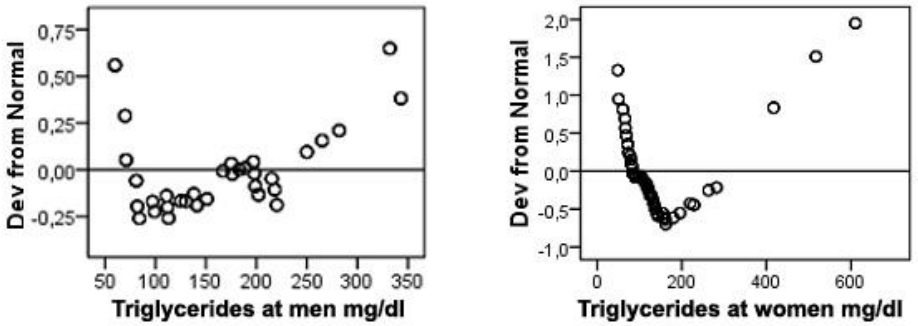

Fig. 2. Distribution of triglycerides values according to sex

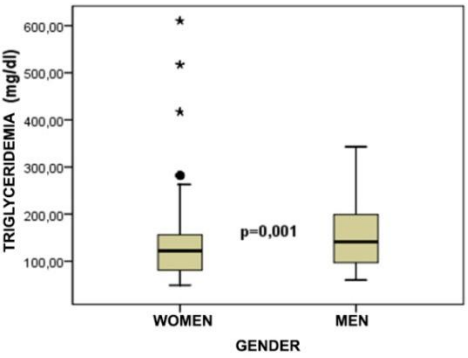

Fig. 3. TG variation by sex

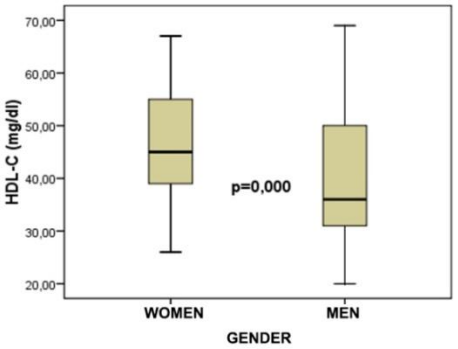

Fig. 4. Variation of HDL-C by sex

HDL-cholesterol

The presence of low HDL-C was found in 193 patients, of whom 97 were men (50.3%) and 96 women (49.7%). The statistical analysis showed a median of 40 mg / dl, with differences according to sex. Analysis of HDL-C values corresponding to the two sexes shows that the distribution of the data is comparable (ANOVA p = 0.032). *Finally*, there is a significant difference between triglycerides values according to sex (fig. 4, 5).

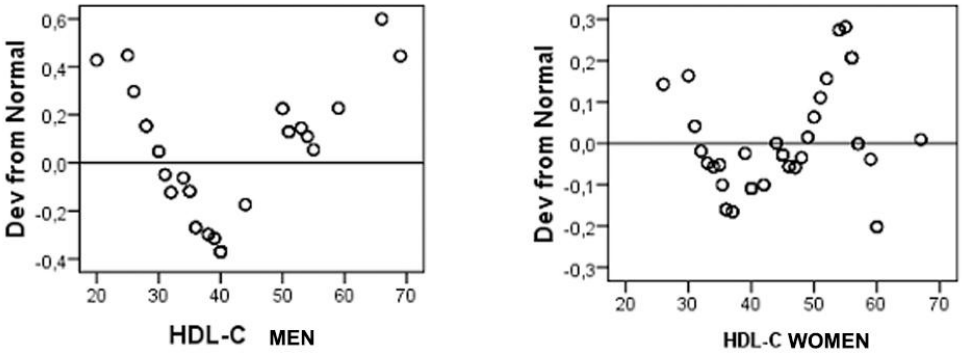

Fig. 5. Distribution of HDL-C by sex

Hypertension

Hypertension was present in 292 patients (86%), of whom 148 were women (56%) and 144 men (44%). The blood pressure median in the study group was 140 mmHg, with a range between 100 mmHg and 200 mmHg, and differences between sexes (fig. 6).

Analysis of BP corresponding to the two sexes showed that the data distribution is not comparable (p = 0.865). *Conclusion*: There is no significant difference between BP values according to sex (fig. 7).

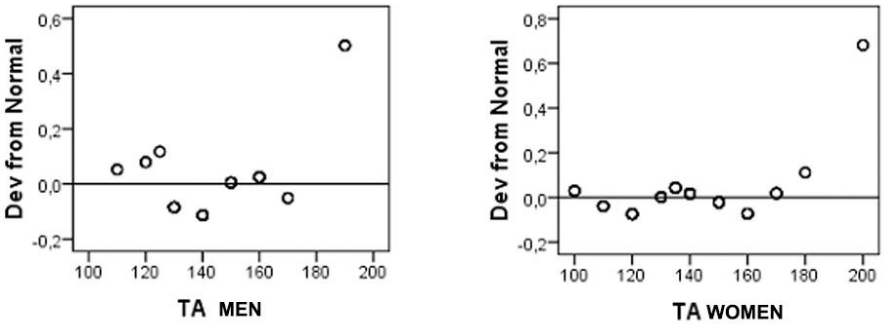

Fig. 6. Distribution of blood pressure (BP) by sex

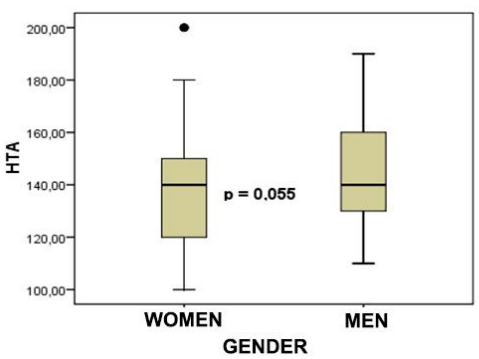

Fig. 7. Variation of BP by sex

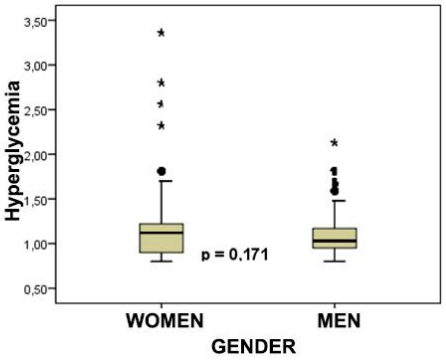

Fig. 8. Variation of glucose values by sex

Glycemic profile

In the study group there were 140 patients with decreased glucose tolerance and 84 patients with DM. The glycemia median in case of the study group was 109 mg / dl, varying between 80-336 mg/dl. The analysis of blood glucose values corresponding to the two sexes shows that the distribution of the data is comparable (ANOVA p = 0.028). The *conclusion* is that there is no significant difference between blood glucose levels by sex (fig. 8, 9).

3. Metabolic syndrome profile

The systematized analysis of the metabolic syndrome profile showed differences according to the sex of patients who were part of the study.

The risk factors studied had the following features:

• AHT was present in 292 patients (86.9%), with no statistical difference between sexes (p = 0.055), 148 women (56%) and 144 men (44%);

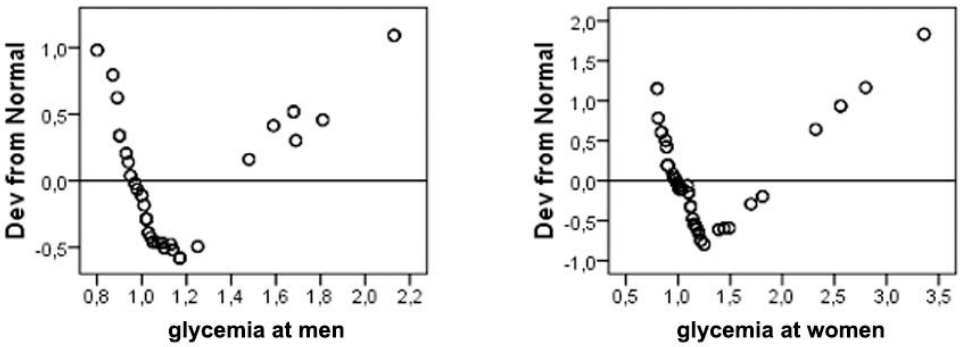

Fig. 9. Distribution of glycemia levels by sex

• hypertriglyceridemia was present in 284 patients (84.5%), with statistical difference between sexes (p = 0.001), 164 women (37.8%) and 120 men (37.8%);

• decrease in HDL-C was found in 193 patients (57.4%), with statistical difference between sexes (p = 0.001), 97 women (50.3%) and 96 men (49.7%);

• abdominal obesity was present in 152 patients (45.2%), with no statistical difference between sexes (p = 0.581), 88 women (57.9%) and 64 men (42.1%);

• change of glycemic profile was recorded in 224 patients (66.6%), without statistical difference between sexes (p = 0.206), 124 women (55.4%) and 100 men (44.6%).

Statistical analysis of Impaired glucose tolerance (IGT) / DM, AHT and increase of TG was present in 172 patients (51%), with no statistical difference between sexes (p = 0.206) in 92 women (53.5%) and 80 men (46.6%) (fig. 10).

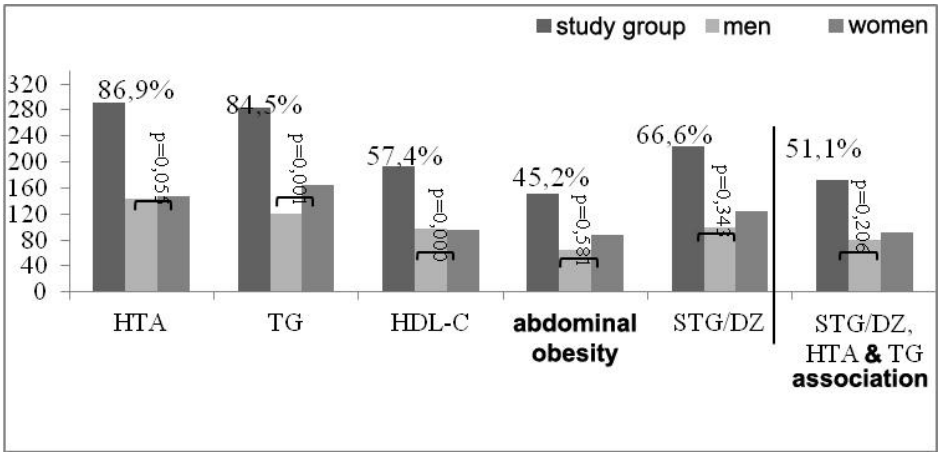

Fig. 10 – Metabolic syndrome profile

4. Cardiovascular risk associated with metabolic syndrome

Patients included in the study were studied depending on the frequency of the main cardiovascular diseases, secondary to metabolic syndrome and of unfavorable

combination of cardiovascular risk factors included in the definition of metabolic syndrome.

Ischemic heart disease

Ischemic heart disease was present in 168 patients (50%), 68 women (40.5%) and 100 men (59.5%), with statistically significant differences between sexes (p = 0.000).

The statistical analysis of the presence of IHD in patients who have in association IGT / DM, AHT and increased TG showed a statistically significant difference compared to those without this association (p = 0.000, Exact Sig. 2-sided).

Ischemic cerebral vascular accident (stroke)

The statistical analysis of the presence of stroke has not showed a statistically significant difference between sexes (p = 0.575, Exact Sig. 2-sided), it was present in 32 patients (9.5%), of whom 16 women (50%) and 16 males (50%). The statistic analysis of this association IGT / DM, AHT and increased TG in patients with ischemic stroke revealed a statistically significant difference compared to those without this association.

Peripheral artery occlusive disease (PAOD)

Peripheral artery occlusive disease was present in 13 patients (3.9%), with statistical difference between sexes (p = 0.019, Exact Sig. 2-sided), in 2 females (15.4%) and 11 men (84.6%). The statistical analysis of this association IGT / DM, AHT and increased TG did not objectify a statistically significant difference (p = 0.251, Exact Sig. 2-sided).

The results of this study were consistent with the literature data in case of hypertriglyceridemia, the other components of MS recording larger differences (9). The effects of IGT / DM, AHT and hypertriglyceridemia association were consistent with literature data, statistically significant in case of IHD's and ischemic stroke (4).

CONCLUSIONS

In the study group the metabolic syndrome profile showed statistical differences according to sex, in situations of HDL-C's decrease, being lower in male patients, and in case of hypertriglyceridemia, the triglycerides level was significantly higher in women.

In case IGT / DM, AHT and hypertriglyceridemia association we recorded an additional risk of development of IHD or ischemic stroke, independent of sex, requiring a multidisciplinary approach including lifestyle changes, pharmacological and surgical treatment (10).

NEWS

CARDIOVASCULAR BENEFITS OF EXERCISE

It is well established that regular exercise results in significant cardiovascular health benefits, including improvements in blood pressure, lipid profile, body mass and composition, as well as objective measures of functional capacity. Moreover, it has been extensively demonstrated that individuals engaging in regular, moderate exercise are at lower risk for mortality, enjoying an average life expectancy 7 years greater than their sedentary counterparts. Such health benefits are evident at relatively modest 'doses' of exercise, amounting to around 6–10 metabolic equivalents per week. Indeed, exercise prescription is among the most cost-effective therapies available for cardiovascular disease prevention, and is devoid of the side effects common to most pharmacological interventions. Incremental benefits in coronary heart disease risk reduction are manifest with increasing activity, such that those achieving around 42 metabolic equivalents per week appear to gain the greatest benefit. By way of example, this would equate to brisk jogging for around 5 h per week. That the beneficial effects of exercise continue to increment above and beyond this point has never been demonstrated.(Abbas Zaidi, Sanjay Sharma. Exercise and Heart Disease. Future Cardiol. 2013;9(1):119-136).

BONE MINERAL DENSITY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE FROM NORTH-EASTERN ROMANIA (Abstract) Inflammatory bowel disease (IBD) is associated with increased prevalence of bone demineralization. One of the risk factors for low bone density is the inadequate level of 25-OH vitamin D. **Aim:** To determine the degree of bone demineralization in patients with IBD and the main causes leading to this condition. **Material and methods:** A prospective study was carried out between April, 2011 and October, 2012 in 143 patients diagnosed with IBD at the Gastroenterology and Hepatology Centre of Iaşi.The IBD diagnosis was made on clinical, biological, and endoscopic criteria and confirmed histologically. The diagnosis of osteopenia/osteoporosis was based on World Health Organization criteria. **Results:** Osteopenia was found in 48.07% of the patients with ulcerative colits (UC) and in 56.41% of the patients with Crohn's disease (CD); osteoporosis was present in 18.26% of the patients with UC and 15.38% of those with CD. The main causes identified were inadequate vitamin D level, extended high-dose corticotherapy in patients with CD, BMI<18.5 kg/m2, and smoking, especially in the patients with UC. **Conclusions:** Bone demineralization and hypovitaminosis D are frequently associated with IBD and require specific treatment. **Keywords**: BONE DEMINERALIZATION, OSTEOPOROSIS, 25-OH VITAMIN D, INFLAMMATORY BOWEL DISEASES.

Low bone density is a condition frequently associated with inflammatory bowel diseases (IBD). The pathogenesis of bone demineralization is multifactorial. Even though the induction mechanisms have not been completely elucidated, the main risk factors are the duration of inflammatory bowel disease, protein-caloric malnutrition, prolonged corticotherapy, calcium and vitamin D deficiency, sex hormones deficit and tobacco consumption (1, 2, 3).

The mineral bone components (calcium and phosphates) are absorbed with the help of 1.25-di-hydroxyvitamin D, the active metabolite of vitamin D. Gastrointestinal tract anomalies, altering their absorption, are factors involved in bone homoeostasis.

According to the World Health Organization (WHO), *osteopenia* is a condition of decreased bone density, while *osteoporosis*is a condition of bone rarefaction, involving the alteration of bone micro architecture

anda secondary increase in fracture risk.

The aim of our study was to determine the degree of bone demineralization in patients with IBD and to identify the main causes leading to this condition.

MATERIAL AND METHODS

A prospective descriptive study was carried out on a series of 143 patients with IBD, hospitalized at the Institute of Gastroenterology and Hepatology in Iaşi between April 1, 2011 and October 15, 2012. The diagnosis of IBD was based on clinical, biological, and endoscopic criteria and confirmed histologically.

The demographic parameters (age, gender, place of residence, type of disease, duration, extension of lesions and degree of activity) as well as the treatment (corticotherapy – months of treatment and cumulative prednisone-equivalent doses) were analyzed. To establish the degree of disease activity, the Crohn's Disease Activity Index (CDAI) and the Ulcerative Colitis Disease Activity Index (Mayo-UCDAI) scores were used. Additionally, the body mass index (BMI) (kg/m²), smoking status and intensity (estimated in packs per year), history of fractures, and, in women, obstetrical antecedents were assessed.

*Exclusion criteria***:** Patients presenting other possible causes of bone demineralization and vitamin D deficiency (bowel resections, thyroid or parathyroid pathology, hypogonadism, diabetes mellitus, neoplasia, renal or hepatic failure, patients with menopause for more than 5 years).

Osteoporosis was assessed by osteodensitometry (biphotonic X-rays absorptiometry = DEXA) at the lumbar spine (L1-L4) and the upper end of the femur. The results were expressed as a T-score (standard deviations below or above the mean value for a younger subject in the general population). WHO classification of bone mineral density was used: normal (T-score > 1DS), osteopenia (T-score between -1 DS and -2.5 DS) and osteoporosis (T-score < -2.5).

The following biochemical values were determined: serum calcium (mg/dl), ionic Ca (mmol/l), alkaline phosphatase (UI/l), 25 hydroxy-vitamin D (ng/ml).

Data analysis was carried out using the *SPSS 16.0* software. The statistical significance threshold was p = 0.05.

In order to test the statistical hypotheses and for continuous and categorical variable data analysis, Student's t and chi-squared distribution were used. The analysis of variance (ANOVA) was used to obtain the statistical indices for the dependent variable (on the whole and by groups), and the Levene test for the analysis of homogeneity of dispersions.

RESULTS

The study included 143 IBD patients divided into two groups: *A:* 104 patients with Ulcerative Colitis (UC) and *B:* 39 patients with Crohn's Disease (CD).

Group A: Most patients (53.84%) were male, mean age 44,65 years. The average duration of the disease was 49.58 months. The extension of lesions was determined based on the Montreal classification; thus, of the 104 patients with UC, 19.23 % had proctitis (E1), 50% left colitis (E2), and 30.76% pancolitis (E3).

As to disease activity, 23.07% of the patients presented severe activity, 25.96% - moderate, 34.61% - slight activity, while 16.34% were in clinical and biological remission.

The body mass index (BMI) was <18.5 kg/m2 in 12 patients (11.5%), normal (BMI=18.5-24 kg/m^2) in 32 patients (30.8%) and high (BMI>24 kg/m^2) in 60 patients (57.69%). Sixty-two patients were

smokers or ex-smokers, with an average tobacco consumption estimated at 15.93 PY (packs-year).

As to UC treatment options, 94,23% of the patients were administered derivatives of 5 aminosalycilates, 42.3% were treated with corticosteroids administered orally or intravenously, with an average prednisone-equivalent dose of 2.82±2.4 g/patient; only 13.5% of the patients benefited from biologic therapy at enrolment.

Osteodensity at the lumbar spine and proximal end of the femur revealed: 34 patients (32.69%) had normal bone mineral density, 50 patients (48.07%) presented osteopenia, and 20 patients (19.23%) osteoporosis (fig. 1).

Group B: Predominantly female patients (53.84%), meanage 39.28 years. The average disease duration was 37.64 months.

Topographically, the Montreal endoscopic classification revealed: 20 colon (L2)-51.28%, ileum and colon-43.58%, while only 5.12% of the patients presented upper digestive tract disorders (L4/ L1+L4).

Disease activity at enrollment: 10 patients (25.64%) were in clinical and biological remission, 12 patients (30.76%) presented slightly-moderate activity, 15 patients (38.46%) – moderate-severe activity, while 2 patients (5.12%) presented highly severe activity. Twenty-two patients (56.41%) were smokers or ex-smokers with an average tobacco consumption of 11.12 PY.

More than half of the patients with CD (61.53%) underwent treatment with corticosteroids administered orally or intravenously, with an average prednisone-equivalent dose of 8.37±21.56 g/ patient. Approximately 30.76% of the patients underwent biological therapy (4 patients with Adalimumab, and 8 patients with Infliximab) at enrollment.

The BMI calculation revealed: 4 patients (10.25%) with CD were underweight (BMI<18.5 kg/m^2), 22 (56.41%) were normal weight, while 13 patients (33.33%) were overweight.

Osteodensiometry at the hip and femoral neck levels revealed 11 patients with normal mineral density, 22 patients (56.41%) with osteopenia, and 6 patients (15.38%) with osteoporosis (fig. 1).

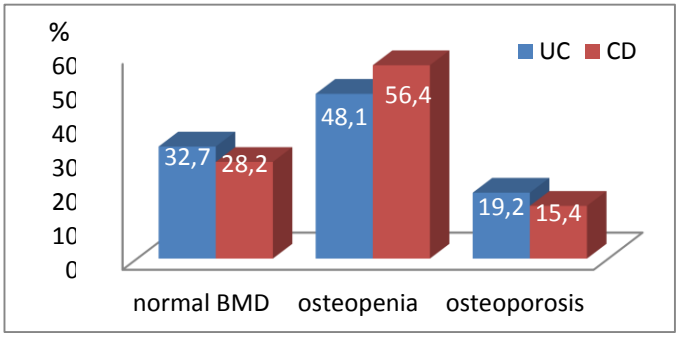

Fig. 1 Bone mineral density in patients with IBD determined by DEXA

Comparing the two 2 groups, it was noticed that bone mineral density was lower in the patients with CD compared to those with UC. T-score for both lumbar spine and hip was lower in CD than UC patients (lumbar spine: CD=-1.60±1.00; UC = -1.00±1.13, proximal end of the femur: CD=-0.93±0.84; UC=-0.31±0.90) (fig.2).

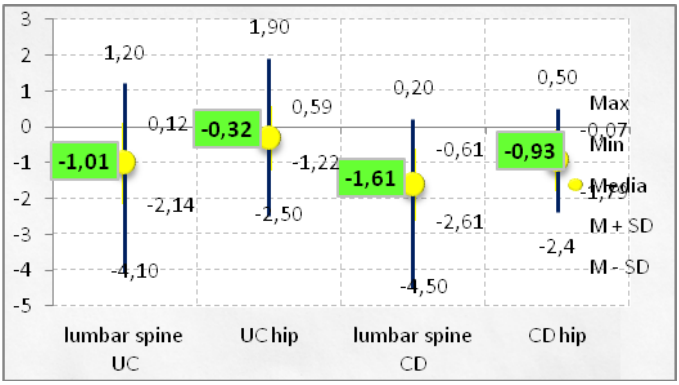

Fig.2. Distribution of the T-score in patients with IBD

TABLE I

Analysis of the risk factors for bone demineralization

Parameters	UC	Crohn's disease	p
BMI < 18.5 kg/m^2	12/104	4/39	> 0.05
Smoker	62/104	22/39	< 0.05
Average tobacco consumption (PY)	15.93	11.12	< 0.05
Average disease duration (months)	49.58	37,64	> 0.05
CS Treatment	44/104	24/39	< 0.05
Average CS dose (prednisone equivalent dose - g/patient)	2.82±2.4	8,37±21,65	< 0.05

As seen, the analysis of the risk factors did not reveal statistically significant differences between the two groups as far as BMI is concerned. Nevertheless, it can be noticed that tobacco consumption was an important risk factor in the patients with UC; moreover, CD patients showed a significantly higher need of corticosteroids, a dose 3 higher/patient compared to UC patients.

25-OH vitamin D determination revealed that CD patients had a significantly lower level compared to UC patients ($p<0.05$) (fig. 3).

There were no statistically significant differences between vitamin D level and the decrease in bone density.

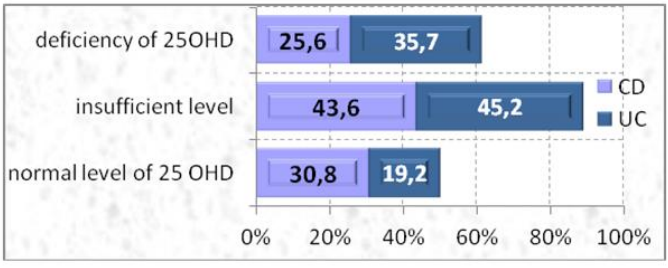

Fig. 3: The level of 25-OH vitamin D in the patients with IBD.

TABLE II

Hematologic and biochemical results in patients with IBD

Marker	UC	CD	p
Average lumbar T-score	-1.00±1.13	-1.60 ± 1.00	**<0.05**
Average hip T-score	-0.31±0.90	-0.93 ± 0.84	**< 0.05**
25-OH vit. D	22 ± 10,71	22.13±9.13	> 0.05
sericCa (ng/dl)	9.42 ± 0.43	9.51 ± 0.37	> 0.05
ionic Ca (mg/dl)	1.22± 0.53	1.19 ± 0.73	> 0.05
Alkaline phosphatase (mg/dl)	84.40 ± 20.82	88.86 ±17.50	> 0.05

DISCUSSION

Over the last years, extended epidemiological studies based on WHO criteria have proven the high prevalence of osteopenia (40-50%) and osteoporosis (10-25%) in the patients with IBD (4, 5). Our study revealed low bone density in 67.3% of the patients with UC and in 71.8% of the patients with CD. Nineteen percent of the UC patients and 15.4% of the CD patients had osteoporosis. These data are in agreement with the data published in the literature. We noticed a smaller percentage of osteoporosis in the patients with Crohn's disease, which can probably be explained by the small number of CD patients compared to UC patients. Osteopenia was found in 48.1% of the UC cases and 56.4% of the CD cases. The obtained data are in agreement with data from similar studies carried out in Italy, Greece and Switzerland (6, 7, 8).

Vitamin D deficiency was significantly higher in the CD patients (35.7%) compared to UC patients (25.6%), despite the fact that the course of UC was relatively longer - 49.58 months compared to 37.64 months in CD. As far as the disease activity is concerned, there were no statistically significant differences. Data in the literature show that 25-OH vitamin D levels vary by season (9). Thus, in all patients, 25-OH vitamin D was determined in the interval May - August (in order to avoid seasonal differences).

The cumulative dose of corticosteroids was inversely correlated with bone mineral density (5, 10, 11). The significant decrease in BMD occurs when the prednisone dose exceeds 7.5 mg/day (5, 12). In our study, it was noticed that approximately 61.53% of the CD patients and 42.3% of the UC patients benefited from treatment with corticosteroids at enrollment or during the disease course, with an average cumulative dose of 8.37 g in the CD group, compared to 2.82 g in the UC group. As to the smoker/non-smoker status, significantly more smokers were found among the UC patients.

Osteoporosis is a condition that can be prevented; thus, a limited use of corticosteroids is recommended, but only in severe activity outbreaks and for a short period. Equally recommended in patients with IBD is osteodensitometry, as early as possible after the diagnosis, since bone demineralization starts early within in the first 2-3 months of disease (5). Some of these patients are young and did not present other risk factors; a bone disease was present at diagnosis in patients with IBD, probably due to the hypovitamnosis D, phenomenon also confirmed by our study.

Osteodensitometry should be repeated every 12-18 months, even though the first

osteodensitometry indicated a normal bone density, since demineralization occurs in time, due to the inflammatory activity of the disease, vitamin D malabsorption and deficient bone calcium deposits.

CONCLUSIONS

Bone mineral density was significantly lower in the CD patients as compared to UC patients. Corticosteroids used in over half of the cases at a dose 3 times higher in CD patients resulted in bone demineralization especially at hip level. 25 OH vitamin D level was lower in the newly diagnosed patients and partially and directly proportionally influenced BMD at the hip level.

Although clinically this complication is noticeable especially with the occurrence of osteoarticular pains and fractures, it requires adequate knowledge and treatment, as well as special attention from gastroenterologists and endocrinologists in order to increase the quality of life of the patients with IBD.

METABOLIC SYNDROME IN OBESE CHILDREN AND ADOLESCENTS

Ana-Maria Pelin[1], Silvia Mătăsaru[2]
University of Medicine and Pharmacy "Grigore T. Popa" - Iasi
1. Ph.D. student
Faculty of Medicine
2. Discipline of Family Medicine

METABOLIC SYNDROME IN OBESE CHILDREN AND ADOLESCENTS (Abstract). **Aim:** To investigate the risk factors for metabolic syndrome (MS) in children and adolescents. **Material and methods:** Investigation conducted in the interval October 2010 - June 2011 in 3103 school children aged 7-18 years. After body weight, height, waist circumference, and blood pressure were measured, 262 school children were found to be obese, of which 120 agreed to testing for defining the metabolic syndrome: triglycerides (TG), cholesterol, HDL and LDL cholesterol, blood glucose, insulinemia, OGTT (oral glucose tolerance test), SGOT, SGPT, urea, creatinine, and ESR. **Results and discussion**: Using IDF 2009 modified criteria, the prevalence of MS in the study series was 55.8%. The most common criteria for defining MS were: TG ≥ 95th percentile, BP ≥ 95th percentile, and blood glucose ≥ 100mg/dl. **Conclusions:** Applying IDF 2009 criteria, 55.8% of the obese subjects presented 3-5 criteria, thus meeting the diagnostic criteria for MS in children. **Keywords:** OBESITY, METABOLIC SYNDROME, CHILD

Child obesity tends to become a global epidemic as both overweight and obesity are increasingly common in developed and developing countries. In recent years, the high incidence was accompanied by an increasing frequency of obesity complications occurring at younger and younger ages (1, 2).

Metabolic syndrome (syndrome X or insulin resistance syndrome) associates obesity (predominantly abdominal), dyslipidemia (hypertriglyceridemia, high LDL, low HDL), arterial hypertension, hyperglycemia, and future risk of developing diabetes, cardiovascular complications and stroke.

There are many controversies about the definition of MS in children. The problem is complicated by the fact that the components of MS syndrome occur progressively and thus not all young patients present a full picture. Furthermore, pathophysiological changes and syndrome components are influenced by growth, and puberty, and not only by gender and ethnicity as in adults (3). Due to these features, adult criteria, IDF (International Diabetes Federation), WHO (World Health Organization), NCEP-ATP III (National Cholesterol Education Program - Adult Treatment Panel III), should be used with great caution in children (4, 5).

For defining the diagnostic criteria for pediatric MS, IDF 2009 modified criteria are divided according to age-groups starting with age 6 years (6).

MATERIAL AND METHODS

The study group included 120 obese

children, selected by overweight screening from 3103 school children aged 7 to 18 years from 8 schools in Galati, Romania. Height, body weight, waist circumference (WC) and blood pressure (BP) were measured, and body mass index (BMI) was calculated; for BMI interpretation the CDC age and gender specific charts were used (7).

In the interval October 2010 – June 2011, after obtaining the informed consent for participation in the study, the 120 obese children (61 girls and 59 boys) were investigated at the Galati "Sf. Ioan" Emergency Children Hospital: triglyceride (TG), cholesterol, HDL and LDL cholesterol, fasting blood glucose, insulinemia, OGTT (oral glucose tolerance test), SGOT, SGPT, urea, creatinine, ESR.

To define pediatric MS we used IDF criteria adapted to children: WC ≥ 90 percentile for age and sex, blood glucose ≥ 100 mg/dl, HDL colesterol ≤ 50th percentile for girls, and ≤ 40 mg/dl for boys, TG ≥ 95th percentile, and BP ≥ 95th percentile for age and sex (8). According to 2009 consensus, the presence of at least three criteria is needed for defining MS, abdominal obesity not being a mandatory criterion.

There are no age-, gender-, race-, and pubertal status-specific insulinemia reference values. In this study we used the following reference values: normal <15 µU/ml, borderline 15-20 µU/ ml, high >20 µU/ml. A mathematical model of glucose-insulin interrelationship, based on a set of feedback loops (Homeostasis Model Assessment = HOMA) was used to draw a graph of the predicted blood glucose and insulinemia values at different degrees of insulin resistance and β –cell deficiency. HOMA-IR index was calculated according to HOMA-IR formula = basal insulinemia µU/ml x fasting glucose (mmol/l)/ 22.5.

Data were loaded and processed using statistical functions of *Excel*, *EpiInfo* and *SPSS*. The used statistical methods were t-Student test, χ^2 test, relative risk, Kaplan-Meier survival curve.

RESULTS

Of the 3103 school children, in 589 (18.9%) weight was over the healthy range for age and height. Of these, 262 (8.4% of all school children) were classified as "obese" having a BMI ≥ 95%. Informed consent to participate in the study was obtained from 120 children and their parents.

Of the 120 investigated obese children, 35 (29.2%) had severe obesity (BMI ≥ 97 percentile for age and gender). Waist circumference (WC), as a marker of visceral obesity and insulin resistance, showed values above the 90th percentile in 69.2% (83 of the 120 obese children), with a slightly higher proportion of males (54, 2%) ($\chi 2 = 2.13$, df = 1, p = 0.144) (fig. 1). There was a correlation between the degree of obesity and waist circumference, the percentage of children with WC above the 90th percentile ranging between 79-83%, in children with moderate and severe obesity this being prevalently visceral (fig. 2).

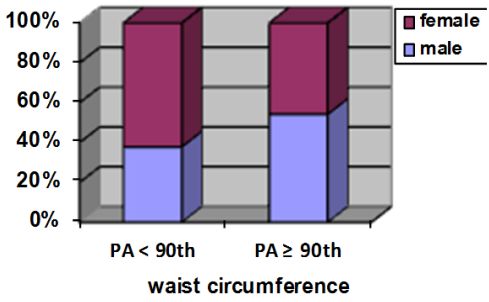

Fig.1. WC and gender correlation

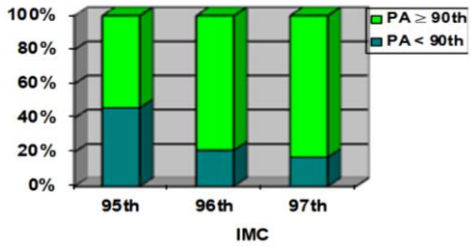

Fig. 2. BMI and WC correlation

The distribution of subjects according to systolic/diastolic blood pressure (SBP/DBP) showed that SBP was above the 95th percentile in 13-14% of the subjects and DBP over the 95th percentile in 9.2% (proportionately, more common in male versus female subjects, 32.2% and 22.9%, respectively, difference statistically insignificant) (fig. 3).

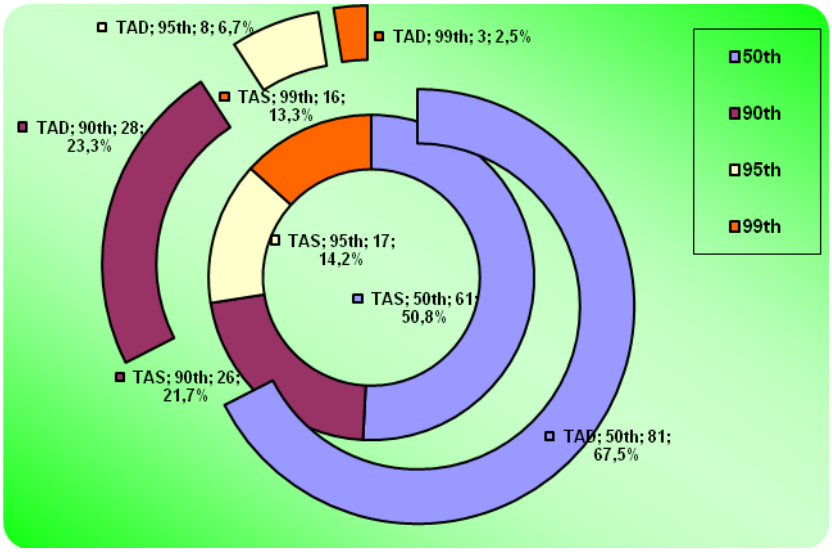

Fig. 3. Distribution of subjects according to blood pressure values

In the study obese children, blood triglyceride levels were: TG ≥ 95th percentile (150 mg/dl): 32 cases (26.6%), TG < 95th percentile (150 mg/dl): 88 cases.

HDL cholesterol levels in the study children were: females - 61 children: HDLc ≤ 50 mg/dl: 46 cases (65.5%), HDLc > 50 mg/dl: 5 cases (34.4%); males - 59 children: HDLc ≤ 40 mg/dl: 39 cases (42.3%), HDLc > 40 mg/dl: 19 cases (57.6%)

Total cholesterol (mg/dl): acceptable level under 170 mg/dl: 62 cases (51.6%), borderline levels between 170-199 mg/dl: 40 cases (28%), elevated ≥ 200 mg/dl: 18 cases (15%).

Fasting glucose levels above the reference values (≥ 100 mg/dl) were found in only 12 of the study children (10%), with no significant gender, BMI and WC differences, all of them meeting the criteria for metabolic syndrome.

OGTT was performed in 108 children, regardless of fasting glucose level or family history, as a measure of obesity. In sample 4, blood glucose levels above 199 mg/dl were found in only a male subject with BMI 95th percentile and WC above the 90th percentile. Glucose tolerance was found decreased in only 2 children, one male and one female, both with WC above the 90th percentile.

Of the 120 investigated children, insulinemia, as a marker of insulin resistance, was determined in only 17. In all these children insulinemia was above 15 µUI/ml. All calculated HOMA-IR values were greater than 3, which can be interpreted as insulin resistance.

MS prevalence in the 120 obese children (BMI ≥ 95th percentile) using IDF 2005 consensus criteria revised in 2009 was 55.8% (67 of 120 children had at least three diagnostic criteria for MS) (tab. I).

TABLE I

IDF criteria for the diagnosis of metabolic syndrome adapted to children by using age and gender specific percentile charts

Diagnostic criteria	Number of cases	Number of cases diagnosed with metabolic syndrome
WC ≥ 90th percentile	83	67 (80,7%)
Fasting glucose ≥ 100 mg/dl	12	12 (100%)
HDLc ≤ 50th percentile	93	67 (72,04%)
TG ≥ 95th percentile	32	32 (100%)
BP ≥ 95th percentile	33	33 (100%)

DISCUSSION

Although components of IDF criteria were present in 72% to 100% of the investigated obese children, only 67 of them (55.8%) met the criteria for MS diagnosis by the presence of at least three of the five criteria.

In our study, of the five IDF 2009 criteria, the most reliable were: triglycerides ≥ 95th percentile, BP ≥ 95th percentile, and fasting glucose ≥ 100 mg/dl (in 100% of the cases that met the criteria for MS diagnosis).

Second in importance was WC ≥ 90th percentile (although 83 of the cases had values suggestive of MS, only 67 met the diagnostic criteria).

Less reliable proved to be HDLc ≤ 50th percentile; although present in 93 of cases, only 67 (72.04%) met at least three IDF criteria for the diagnosis of MS.

This study along with numerous other studies, confirms that MS is present not only in obese adults but also in obese children, even though the clinical and biological picture is not complete at this age, it gradually progressing with advancing age.

Longitudinal studies are needed to assess the evolution of these parameters in relation with advancing age and maintenance or not of obese status.

Data reported by various researchers on the incidence of MS in obese people range between 11.5% and 60-80% in relation to patient age, degree of obesity, ethnicity, presence or absence of diabetes mellitus.

The incidence of MS in child obesity is still insufficiently studied, and the reports differ because they do not use the same evaluation criteria, which have changed over time. For example, when the same group of obese people was assessed by different criteria, MS was present in different percentages (10): IDF 2009 criteria = 58%, NCEP-ATP III criteria = 42 %, and WHO criteria = 10%. Another important issue is the gradual occurrence and worsening with time of its manifestations, so that the percentage will vary with study series age homogeneity. In the present study, the percentage of obese children in which MS by the presence of at least three IDF criteria began to develop is 55.8%. These results, surprising at first sight, are however in agreement with those published by Preda

that found 58% (9). However, regardless of used definition, the prevalence of MS was significantly higher in obese (42.9%) compared to normal weight people (2.8%) (10).

The above data clearly show that the phenomenon occurs and needs to be stopped even during childhood, when manifestations are not yet severe or irreversible as in the elderly. From this perspective, children and youth are an important target group because early healthy eating habits along with a healthy lifestyle make the most effective method of living in health. School and education are a means and an important environment for overweight prevention and WHO identified school as the main starting point in the fight against obesity (11, 12).

CONCLUSIONS

In our study, of the 3103 school children (7-18 years), 589 (18.9%) were overweight for age and height, and 262 (8.4% of children) were obese having a BMI $\geq$ 95.

MS (IDF 2009 criteria) was recorded in 55.8% of the 120 obese school children from which the informed consent for participation in the study was obtained.

The need for longitudinal studies to evaluate the evolution of these parameters in relation to patient age and maintaining or not obese status is emphasized.

STUDY ON THE EFFECTIVENESS OF THE KINETIC METHOD IN PATIENTS WITH RHEUMATIC DISEASES AND TEMPOROMANDIBULAR JOINT DYSFUNCTION (Abstract): selecting the appropriate treatment decision is essential for achieving optimal results in the management of algo-dysfunctional syndrome of the temporo-mandibular joint (TMJD). The study aims to decide on the most effective (symptomatic control, preserved motility) kinetic program in patients with TMJ involvement. **Material and Methods**: prospective observational study on 83 consecutive patients with rheumatic diseases and TMJ dysfunction. Clinical assessment (pain, noises, muscle spasm, range of motion, ROM) was performed at baseline and after 3 months of specific kinetic rehabilitation program. Change in clinical parameters and TMJ index was reported, $p<0.05$. **Results**: over 45% TMJ involvement at baseline as defined by TMJ index (mean value of 13.56) and only 36.66% at 3 months ($p<0.05$). Significant improvement in pain (presence, severity) was demonstrated at 3 moths ($p<0.05$): 18.05% spontaneous pain, 75.9% provoked pain, with 12.11% respectively 2.41% decreased in nocturnal respectively diurnal pain. Significant decrease ($p<0.05$) in joint noises at movements: 27.71% when opening and 12.04% when closing the mouth, 8.43 at protrusion and 3.61% at retraction, while 18% at the side movements. **Conclusions**: Complex accurate kinetic reeducation is mandatory for achieving correct posture (head, neck and trunk), normal mastication, swallowing and respiration, as well as correction of neuromuscular imbalances in patients with TMJD secondary to rheumatic disorders. **Key words:** TEMPORO-MANDIBULAR JOINT DYSFUNCTION, THE FUNCTIONAL ASSESSMENT, TREATMENT, REHABILITATION.

About 40% to 70% of adults have experienced at least one symptom related to the temporo-mandibular joint dysfunction (TMJD), but in the majority of cases it was treated superficially leading to worsening of the symptoms. Due to the complexity and variability of the manifestations, the painful TMJD can initiate significant structural and functional changes, finally leading to impaired work capacity, reduce opportunities to carry out daily activities, and subsequent impaired quality of life (1).

Both inflammatory and degenerative rheumatic conditions may secondary involve TMJ being responsible for a range of pain and mandible dysfunction. (2). Pain, joint cracklings and affected restricted range of motion (ROM) are the mainstay of the clinical background of TMJ participation (2). Therefore, it is widely recognized that the kinetic therapy, through its effects and the applied noninvasive methods, can improve the existing symptoms and may change the patient's opinion regarding the condition of suffering.

Establishing a treatment plan customizes all general data regarding the clinical, functional and laboratory aspects, as well as the synopsis of all clinical and biological, functional, psycho-socio-economic and behavioral indices. Subsequent kinetic approach requires an accurate functional diagnosis of the TMJ involvement and a choice of the optimal therapeutic solution, based on the theoretical and practical achieved experience, but also on general and local treatment.

Moreover, the kinetic treatment is essential in the setting of persistent TMJD aiming to maintain or restore the functionality at this level leading to structural, functional and aesthetic changes. Choosing the appropriate treatment plan coupled with appropriate therapeutic management is the ideal option for achieving superior results in the treatment of the painful-dysfunctional syndrome of the TMJ.

Given the complexity and variability of the algo-dysfunctional TMJ syndrome, the current study aims to decide on the most effective kinetic program in patients with TMJ involvement.

MATERIAL AND METHODS

We performed a prospective observational study during October 2009 and September 2011 on eighty-three consecutive patients with different inflammatory and degenerative rheumatic disorders and secondary TMJ involvement in order to elaborate a complete and correct protocol for TMJD evaluation and treatment.

The study was approved by the Ethics Committee and all patients signed the informed consent before enrollment.

Clinical signs and symptoms of the TMJ involvement were systematically registered at baseline and at three months, including: pain, muscle spasm, noises and bruxism, as well as range of motion (ROM).

Specific medication, physical and kinetic management were promoted in all patients according to the disease and the stage (acute, sub acute, chronic) of the TMJD, aiming to control muscle spasm, referred pain and to restore mandible motility rebalancing the agonist and antagonist muscles groups of the neck and face and proprioceptive recovery. Orthodontic care was required to restore normal occlusion.

All patients were included in a complex kinetic program: 3 sessions per week for the first two weeks, 2 sessions per week for the next two weeks and 1 session per week up to 3 months. The duration of a session was settled between 60 to 90 minutes, intending to obtain the local and general relaxation of the patient.

Several methods and rehabilitation techniques were currently used including general massage of the head and neck; relaxing massage for muscles spasm control (temporalis, masseter, medial and lateral pterigoids, suprahyoids, infrahyoids, digastrics); techniques for detecting and treating trigger points (face, head, neck); passive and active stretching exercises lowering of the mandible, side movements, protrusion and retraction; passive stretching exercises performed through specific movements of the trunk and neck; techniques of intra- and extra-oral mandible

manipulation; resistance exercises for opening and closing the mouth; corrective exercises for posture (head, neck, trunk); proprioceptive exercises of TMJ; diaphragmatic breathing exercises and swallowing rehabilitation exercises.

Statistical analysis. Both descriptive (mean, standard deviation, percentage) and analytic statistics (t-test) were used to analyze difference between visits; statistical significant "p" was settled below 0.05.

RESULTS

Pain

Baseline clinical exam has revealed TMJ pain at palpation (external auditory canal, pretragus, jaw muscles) and mobilization of the mandible, but also during chewing in all patients. After three months, we demonstrated the decrease in pain intensity, as well as the increase in the number of patients presenting moderate and mild pain compared to the initial assessment as shown in figure 1; besides, two patients had no pain. Only 18.05% of cases presented with spontaneous pain and up to 75.9% provoked pain at visit 2; in addition we reported a decrease of 12.11% in the nocturnal pain and 2.41% in the diurnal TMJ pain.

Noises

At the initial assessment 50% of the analyzed cases complained noises at the level of the TMJ: more advanced stage of the disease, more frequent noises in the joint. After three months of treatment we revealed the decrease, even the absence of the joint noises during different movements as follows: 27.71% noises when opening the mouth, 12.04% noises when closing the mouth, 8.43% at protrusion, 3.61% at retraction, while 18.07% of cases presented with noises at the side movements (fig. 2).

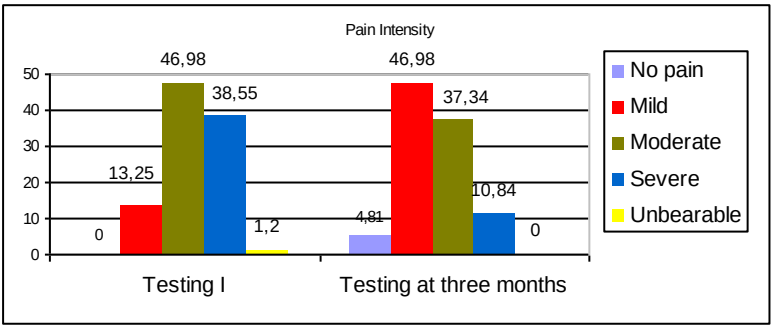

Fig. 1. Pain evidence in tested patients

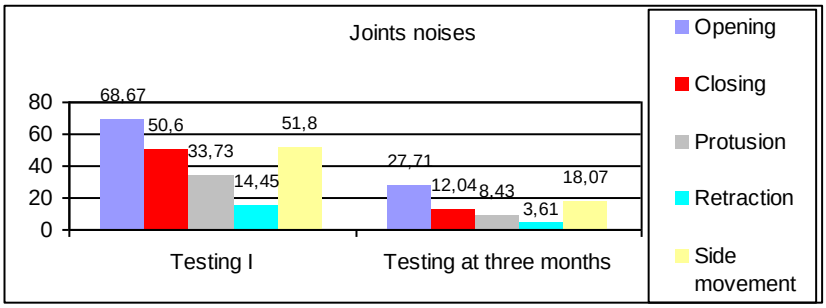

Fig. 2. Joint noises

Muscle testing

The manual muscle testing was performed in all patients on masseter, temporalis, medial and lateral pterigoid, digastric, sternocleidomastoidian and longus colli muscles, looking for the presence of pain, spasm and atrophy. The initial testing showed pain in the majority of cases (84.61%) in the masseter muscle, as well as in 65.38% of cases in the temporal muscle, the main masticators muscles. After three months of specific kinetic treatment, we demonstrated a decrease of pain in the tested muscles, about 25 to 30%. Keeping the same algorithm of muscle pain, the main masticators muscles (temporal, masseter) remained the most affected.

Muscle spasm and muscle atrophy

Muscle spasm was accompanied or caused by pain and was reported at baseline in about half of patients (51.91%) in the masseter, 26.92% in the temporal, 13.46% in the median and lateral pterigoids, and in 17.30% in the sternocleidomastoidian muscle. Muscle spasm significantly decreased ($p<0.05$) after three months of treatment and allowed proprioceptive mandible movements in various positions with increasing amplitude and severity.

On the other hand, muscle atrophy was present in a small proportion of patients as compared with other parameters both in the initial and final testing.

Range of motion

Baseline assessment showed a decrease in the ROM at the TMJ as follows: 15.38% for opening of the mouth, 29.9% for the side movement, 21.15% for protrusion, 1.92% for the retraction movement. Limitation of the mandible mobility resulted in diet restriction, disruption of daily activities and impaired quality of life. After three months of kinetic treatment, ROM at the TMJ significantly ($p<0.05$) improved, the majority of patients showing even normal parameters, with significant progress of quality of life.

TMJ index

Furthermore, a TMJ index was calculated for each patient; the TMJ index is centralizing data on pain (severity and duration), joint noises, vicious habits, joint ROM and muscle status. We obtained an average value 13.56 at the initial testing, meaning a TMJ involvement of over 45%. After three months, TMJ involvement was reported in only 36.66%, indicating a decrease in joint dysfunction along with an increase in the physical and psychological comfort of the patients (fig. 3, tab. I).

TABLE I

Analysis of the TMJ index

TMJ INDEX	No	MED	Standard deviation
Initial Testing	83	15.01	3391
Testing after 3 months	83	11	2798

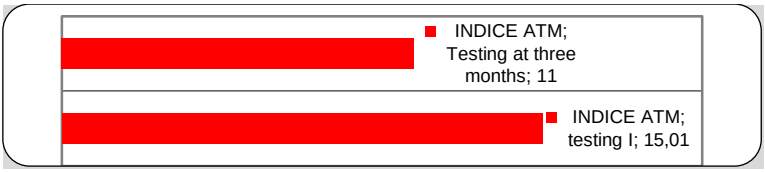

Fig. 3. Evolution of the TMJ index

Moreover, in our study we obtained a correct posture of the head, neck and trunk, a normal mastication, deglutition and respiration, as well as the increase of the range of motion in the TMJ, overcoming the neuromuscular imbalances.

DISCUSSION

It is actually widely recognized the benefit of kinetic therapy in the rehabilitation of the algo-dysfunctional syndrome of the TMJ, with subsequent improvement of quality of life (3). Besides, key goals of the rehabilitation process in patients with different rheumatic conditions affecting TMJ involve: local and general relaxation; the control of the painful symptoms, muscle spasm and residual tensions; the increase of the range of motion; the restoration of the morphology and aesthetic aspect of the face. Rebalancing the agonist and antagonist muscle groups of the neck and face, muscular coordination, proprioceptive rehabilitation, as well as restoration of the normal body movement through an accurate mental representation of different mandible functions and maintaining a correct posture of the head, neck, trunk and scapular-humeral joint are also promoted in the complex TMJ rehabilitation process (1, 6). All these objectives can only be achieved by an early, aggressive, sustained and continuous treatment.

Three main stages are actually recognized in active rehabilitation of TMJD including rehabilitation through visual control of the patient, rehabilitation of the patient without visual control, only by touch and the performance of the movements without visual or tactile control, proprioceptive rehabilitation(4).

In the current context of modern medicine emphasizing the weight of patient's comfort and quality of life, we have quoted the relationships that can be established between different therapeutic backgrounds and the clinical-biological, socio-economical and psycho-behavioral parameters, as well as the individual post-therapeutic feedback.

The TMJ index shows the degree (%) of the global dysfunction of the TMJ; in our study the assessment of this index was systematically done in all patients indicating a positive course of TMJD and demonstrating the benefit of complex kinetic approach. Furthermore, we have demonstrated a significant improvement in all parameters defining the TMJ index including pain, muscle and joint involvement.

After three months of kinetic treatment, only 37% of patients presented with dysfunction of TMJ secondary to different rheumatic disorders; data was comparable with the literature (6).

It can be assumed that complex multidisciplinary (rheumatologist, dentist, kinetic therapist, physiotherapist and psychologist) work-team is essential for achieving positive results in the rehabilitation of patients with algo-dysfunctional syndrome of the TMJ. In addition, the active role of patient should also be mentioned. The main goal of the rehabilitation team is to improve as much as possible the TMJ status, to restore the patient's capacity to live in an integrated manner, physically and psychosocially and, finally, to improve quality of life. The complex issues generated by the algo-dysfunctional syndrome of the TMJ capture and attract the interest of practitioners and researchers in the field. Therefore, our research has tried to highlight new emerging concepts on TMJ rehabilitation, particularly in the settings of rheumatic field.

CONCLUSIONS

Correct and complex analysis of patient's medical records (medical history, clinical and functional laboratory tests) is essential in order to provide the optimal therapeutic approach.

The kinetic program depends on the quality of therapist-patient communication, motivation, perseverance, as well as patient collaboration, being the most important issues in TMJ rehabilitation. Clear, well established objectives should be encouraged advancing long-term improvements. A short-term care is classically associated with increased risk of the recurrence and, even, complications.

Furthermore, accurate kinetic recovery is a prerequisite condition for a proper mastication in patients with algo-dysfunctional TMJ syndrome.

A significant improvement in the TMJD syndrome was reported after the kinetic management in patients with various (inflammatory, degenerative) rheumatic disorders and secondary TMJ involvement as suggested by the modification of the TMJ index, leading to better quality of life.

REZISTENȚA LA CLOPIDOGREL – FACTOR DE RISC PENTRU PACIENȚII CU SINDROAME CORONARIENE ACUTE

CLOPIDOGREL RESISTANCE – RISK FACTOR IN PATIENTS WITH ACUTE CORONARY SYNDROMES (Abstract): Clopidogrel is an ADP receptor antagonist, an inhibitor of platelet activation and aggregation. The effect is due to its selective and irreversible blockade of the P2Y12 receptor. The concept of clopidogrel resistance emerged since several years ago. This biological finding has a very important impact especially in patients with acute coronary syndromes, explaining by this their worse evolution. Mechanisms of this resistance are very complex including: differences in intestinal absorption, hepatic conversion to the active metabolite through cytochrome 3A4 (CYP3A4) activity, drug interactions, individual variations in the activity of hepatic cytochrome P450 izoenzymes, platelet receptor polymorphisms and also clinical factors. According to this resistance patients are divided in two groups : "low or non-responders" (with a high risk of thrombosis) and "high - responders" (with a high risk of bleeding). Carriers of CYP2C19*2 or *3 alleles have been shown to respond poorly to standard doses of clopidogrel due to reduced metabolic activation of the drug. So, they are likely to develop subsequent thrombotic events. Starting from these, a lot of studies have been performed in order to elucidate the mechanisms of this resistance offering new perspectives regarding a proper administration of antiplatelet therapy in patients with acute coronary syndromes. **Key words:** CLOPIDOGREL, ACUTE CORONARY SYNDROME, GENETIC POLYMORPHISMS

Sindroamele coronariene acute (SCA) definesc un spectru larg de afecțiuni clinice: angina instabilă, infarctul miocardic non-Q şi infarctul miocardic cu supradenivelare de segment ST. Evoluția şi, implicit, prognosticul acestor bolnavi rămâne o problemă importantă, care impune o spitalizare selectivă şi adesea repetată, în special a celor cu risc crescut. Riscul cumulat pentru un eveniment ischemic în timpul fazei acute şi al următoarelor trei luni postevenIment este de aproximativ 50%, datorită timpului lung necesar stabilizării plăcii aterosclerotice (1). Pacienții cu SCA au un risc major de apariție a unor complicații severe ajungînd uneori la deces. Medicația antiplachetară constituie baza tratamentului antitrombotic în SCA, eficiența ei având dovezi incontestabile, datorită numeroaselor trialuri randomizate (2). În ultimii 10 ani s-au realizat progrese remarcabile în ceea ce priveşte strategia terapeutică a

SCA, inclusiv în terapia antiplachetară, incluzând dozele utilizate, durata tratamentului şi folosirea terapiei duale sau triple cu aceşti agenţi (3). SCA au un substrat anatomic comun, iar observaţiile anatomopatologice, angioscopice şi biologice au demonstrat că angina instabilă şi infarctul miocardic reprezintă în realitate aspecte clinice diferite ale unui mecanism fiziopatologic comun, respectiv ruptura sau eroziunea plăcii aterosclerotice, cu grade diferite de tromboză şi embolizare distală supraadăugate (4). Terapia antiplachetară este în mod curent folosită la pacienţii cu risc înalt de aterotromboză şi a devenit „*piatra de temelie"* în tratamentul bolii coronariene (5). În pofida succeselor obţinute în domeniul terapiei antiplachetare, pacienţii ce urmează un asemenea tratament au un risc crescut pentru producerea unui eveniment trombotic nou (6). Tienopiridinele (ticlopidina şi clopidogrelul) sunt inhibitori ai adenosin difosfatului (ADP), ducând la inhibarea agregării plachetare. Ticlopidina a fost investigată într-un singur studiu (7), intoleranţa la acest medicament fiind relativ frecventă datorită tulburărilor gastrointestinale sau reacţiilor alergice. În plus, ca efecte secundare mai pot apare neutropenia sau trombocitopenia. Din acest motiv, ticlopidina a fost înlocuită de clopidogrel care este unul dintre cei mai recomandaţi inhibitori plachetari la nivel mondial, cu toate că farmacodinamica variază substanţial la nivelul individual (8), astfel încât pacienţii cu răspuns suboptimal manifestă un risc major pentru un eveniment cardiovascular nou (9). La pacienţii cu sindroame coronariene acute, clopidogrelul se recomandă atât pentru tratamentul acut cât şi pentru cel de durată, de minim 9-12 luni. Acest preparat poate fi recomandat şi pentru terapia imediată sau de lungă durată la pacienţii care nu tolerează acidul acetilsalicilic (10), precum şi celor la care s-a implantat un stent (11). De-a lungul timpului au fost realizate teste pentru evaluarea gradului de inhibiţie plachetară la pacienţii trataţi cu clopidogrel: LTA – *light transmision aggregometry* ("standard de aur'' pentru predicţia evenimentelor cardiovasculare), VASP – *vasodilator stimulated phosphoprotein* şi PRI – *platelet reactivity index* (12). VASP este considerat ca fiind cel mai specific test pentru identificarea gradului de inhibiţie a receptorului plachetar P2Y12 (13). Unele studii au evidenţiat efectul inhibitor al clopidogrelului în combinaţie cu acidul acetilsalicilic (14). Cu toate că în cazul clopidogrelului beneficiul clinic a fost demonstrat, variaţiile genetice individuale, ar putea explica inhibiţia plachetară insuficientă, care reprezintă factorul de risc major pentru un nou eveniment trombotic. Conceptul de „*rezistenţă la clopidogrel"* datează de câţiva ani şi are două implicaţii: una clinică - legată de evoluţia şi implicit prognosticul nefavorabil al unora dintre pacienţii cu SCA şi, cea de a doua – practică, care implică necesitatea introducerii în uz a unor noi agenţi antiagreganţi plachetari, care să nu dezvolte fenomenul de rezistenţă (15). Studii recente (16) au arătat că aproximativ 31% dintre pacienţii cu SCA prezintă rezistenţă la Clopidogrel, aceasta fiind definită ca răspuns slab în ceea ce priveşte antiagregarea plachetară, această categorie de pacienţi având implicit o evoluţie clinică şi un prognostic nefavorabile. Printre enzimele hepatice care sunt implicate în acest proces, un rol cheie îl are citocromul CYP2C19, care la rândul său prezintă numeroase izoforme răspunzătoare de variaţiile activităţii catalitice, corelate cu variaţiile procesului de conversie al clopidogrelului în

metaboliții săi activi. Din punctul de vedere al vitezei de conversie a clopidogrelului pacienții pot fi metabolizanți lenți sau rapizi. Astfel, unii pacienți (”low – responders” sau ”non-responders”) pot prezenta un răspuns slab sau lipsă de răspuns în ceea ce privește procesul de antiagregare plachetară (urmarea fiind riscul crescut de tromboze). În această categorie se încadrează şi pacienții cu tromboză precoce intrastent (17). Altă categorie de pacienți (aşa- numiții ”high – responders”) prezintă un răspuns exagerat manifestat clinic prin risc crescut de sângerare.

În privința mecanismelor acestei rezistențe au fost emise mai multe teorii. Studiile de farmacocinetică au demonstrat faptul că clopidogrelul este un medicament care necesită o serie de transformări pentru a genera metabolitul activ, acesta din urmă fiind inhibitorul real al receptorului ADP, P2Y12 (18). După absorbția la nivel digestiv, 85% din doza de Clopidogrel este hidrolizată de către esteraze într-un metabolit lipsit de activitate antiagregantă. Restul de 15% urmează două trepte de oxidare care implică citocromul P450s şi astfel este generat metabolitul activ, care se leagă ireversibil de receptorul P2Y12, inhibând astfel agregarea plachetară. Transformarea „*in vivo*”, a prodrogului – clopidogrel, în metabolitul activ, reprezintă un pas critic în atingerea efectului antiplachetar. Clopidogrelul transformat în metabolitul activ, care blochează receptorul ADP - P2Y12, inhibă astfel activarea plachetară mediată de ADP. Această metabolizare este dependentă de activitatea izoenzimelor hepatice aparținând familiei citocromului P450 (CYP2C19, CYP1A2, CYP2B6, CYP2C9 şi CYP3A4). Răspunsul la clopidogrel este în consecință influențat de o cascadă de reacții răspunzătoare de formarea metabolitului activ (19). Metabolizarea clopidogrelului la nivel hepatic are ca prim pas transformarea acestuia în 2-oxo-clopidogrel, urmată de conversia în metabolitul activ**.** Citocromii CYP1A2, CYP2B6, CYP2C9 şi CYP3A4/5 sunt recunoscuți ca fiind implicați în metabolismul clopidogrelului, dar importanța fiecăruia, cât şi etapa exactă în care aceştia sunt implicați este controversată (20). Anumite publicații (21) indică CYP3A4 ca factor major implicat în metabolismul clopidogrelului, în timp ce altele conferă citocromilor CYP1A2, CYP2B6 şi CYP2C19 acest rol (22). Kazui *et al.* (23) au arătat că CYP2C19 contribuie substanțial la metabolizarea clopidogrelului, în timp ce CYP3A4 are rol doar în conversia în 2-oxo - clopidogrel. Conform altor studii (24, 25, 26, 27, 29), nu ar exista o legătură directă între CYP3A5 şi efectul antiplachetar al clopidogrelului. În prezent, cel puțin 25 de polimorfisme ale unui singur nucleotid (*single nucleotide polymorphisms* - SNP), au fost descrise în gena care codifică CYP2C19, din care alela CYP2C19*2 (exonul 5), este cea mai cunoscută şi studiată. Ea se pare că induce o scădere semnificativă a concentrației de metabolit activ seric şi reduce astfel inhibiția agregării plachetare (24). Prezența alelei ce determină pierderea funcției enzimatice (CYP2C19*2) este cel mai studiat polimorfism, fără a exista, însă, un consens. Lee *et al.* (25) au arătat că există diferențe etnice în ceea ce privește frecvența polimorfismelor. Se pare că alela CYP2C19*3A este mai frecventă în populația asiatică decât în cea americană (25), considerându-se că 20-30% din populația SUA este heterozigotă pentru polimorfismele CYP2C19*2, în timp ce 2-3% sunt homozigoți, cu activitate enzimatică nulă, date similare celor din populația europeană (26). Deşi celelalte SNP sunt rare, sunt

necesare studii suplimentare, pentru a elucida rolul mai puțin cunoscut al acestor polimorfisme CYP2C19. Recent a fost raportat că heterozigoții compuși CYP2C19*3A - CYP2C19*2A, au un risc crescut de tromboză acută intrastent (27). Pacienții tratați cu clopidogrel și care au alela CYP2C19*2A, ar avea un risc crescut pentru evenimentele ischemice recurente (28), prin comparație cu alela CYP2C19*17 care a fost asociată cu o exacerbare a activității enzimatice, fiind considerate o mutație cu „câștig de funcție", care poate crește riscul de sângerare în timpul tratamentului cu clopidogrel (29). Studii recente au evidențiat influența variantei alelice C3435T (rs1045642) a genei *ABCB1* în absorbția la nivel intestinal a clopidogrelului la pacienții cu boli cardiovasculare (30).

Aceste evidențe susțin pe de o parte ideea necesității unor teste sau determinări care să identifice pacienții ce ar putea prezenta acest fenomen de rezistență, înainte de începerea tratamentului, iar pe de altă parte se impune realizarea unor preparate noi care să inducă fenomenul de rezistență și, eventual, să nu necesite metabolizare hepatică.

În prezent, cele mai cunoscute, specifice și sensibile metode de determinare a SNP-urilor (care pot varia în funcție de polimorfismul vizat), sunt:

- **TaqMan assays** (Applied Biosystems, Life Technologies, Pleasanton, CA, USA)**,** care se bazează pe discriminarea alelică prin Real-Time PCR în sistem TaqMan. Pentru fiecare alelă este utilizat același set de primeri și câte o sondă cu fluorescență specifică. Prin degradarea sondelor de către polimerază (cu proprietați exonucleazice 5'-3'), în timpul amplificării se va emite (doar de către sonda hibridizată), o anumită fluorescență. Aceasta va permite discriminarea alelică sub forma unui cod de culori ;

- **Reverse Hybridization** se bazează pe o amplificare PCR, urmată de hibridizarea ampliconului format, pe un „*strip"*, marcat în prealabil cu sonde specifice fiecărei alele, pentru ca apoi, printr-o reacție cu un anticorp biotinilat și o enzimă, să se obțină o reacție de culoare caracteristică;

- **Secvențierea** ampliconului de interes este singura metodă capabilă să identifice toate mutațiile și polimorfismele din regiunea de interes. De asemenea, secvențierea este și o metodă de validare a rezultatelor obținute prin metodele alternative, dar rămâne o metodă complexă, consumatoare de timp și fonduri.

NOUTĂȚI

ROLUL TOR ÎN REGLAREA CELULELOR STEM

Factorul țintă al rapamicinei (TOR - Target of Rapamycin) controlează un sistem de semnalizare care modulează creşterea celulară şi diviziunea prin detectarea nivelurilor de nutrienți, energie şi stress. Semnalizarea mediată de TOR este o componentă crucială a țesuturilor şi organelor, care traduce semnalele în comportamente celulare. TOR are rol în apariția neoplaziilor, a bolilor degenerative şi în procesul de îmbătrânire, dar modul de acțiune nu a fost foarte clar elucidat. Natura ubicuitară a semnalizării TOR şi dificultatea analizării țesuturilor în cursul turnover-ului au limitat înțelegerea modului în care această kinază funcționeză în organism. Viermii Planaria au reprezentat un model experimental pentru studiul reglării TOR la nivelul organismului. Aceşti viermi sunt cunoscuți pentru capacitatea lor de regenerare celulară, iar studiul lor ar putea oferi noi indicii privind elaborarea unor terapii anticanceroase. TOR are un rol esențial în regenerarea celulară la Planaria, inhibiția sa împiedicând creşterea acestor viermi. Aceste observații sugerează că blocarea TOR în celulele care prezintă anomalii ar putea preveni proliferarea neoplazică. Smed-TOR, un omolog al TOR de la planarii este exprimat ubicuitar, inclusiv de către celulele stem şi țesuturi diferențiate. Inhibiția TOR prin interferența ARN inhibă proliferarea celulară, permițând studiul neoblaştilor cu o capacitate proliferativă redusă în cursul regenerării şi turnover-ului celular. Semnalizarea TOR este necesară pentru răspunsul neoblaştilor la amputație şi proliferarea la nivel de blastema. În absența semnalizării TOR, regenerarea are loc doar în țesuturile diferențiate. În plus, TOR este esențial în menținerea echilibrului între diviziunea celulară şi moartea celulară, iar disfuncționalitățile acestui sistem duc la degenerare tisulară şi lipsa creşterii în prezența nutrienților. PULMONARY TOXOPLASMOSIS IN IMMUNOSUPPRESSED PATIENT– (Abstract): Pulmonary toxoplasmosis occurs mainly in immunosuppressed patients and its diagnosis mainly relies upon biological confirmation of the parasite. We present the case of a 47 years patient in medullar aplasia after induction chemo-therapy for acute lymphoblastic leukemia that developed pulmonary infiltrates of parasitic origin. The diagnosis of pulmonary toxoplasmosis was established after identification of the parasite in brochioloalveolar lavage fluid (BAL) and peripheral blood. Serological tests are of limited utility in immunosuppressed patients. We used classical methods for the diagnosis of parasitosis but they are being replaced by molecular methods. Polymerase Chain Reaction (PCR) allows a highly specific and sensitive diagnosis on any sample but it cannot be performed in any center. **Key words:** PULMONARY TOXOPLASMOSIS, IMMUNOSUPPRESED PATIENT, BRONCHIOLOALVEOLAR LAVAGE FLUID, CEREBRAL LESIONS.

Toxoplasmoza este o infecţie parazitară insidioasă, frecvent oligo-simptomatică şi insuficient diagnosticată, al cărei agent etiologic este *Toxoplasma gondii***.** Ciclul parazitului implică gazdă definitivă pisica sau unele feline sălbatice, iar cea intermediară, poate fi reprezentatăde orice mamifer vertebrat, inclusiv omul (1).

Cele două forme parazitare sunt reprezentate de tahizoid, care se multiplică intratisular şi bradizoid, o formă rezistentă intrachistică. Gradul afectării organelor şi sistemelor, severitatea manifestarilor clinice, evoluţia bolii şi prognosticul depind de integritatea sistemului imun (2, 3).

MATERIAL ŞI METODE

S-a inclus în studiu pacientul M.T. în vârstă de 47 de ani, diagnosticat cu leucemie limfoblastică acută, supus chimioterapiei de inducţie cu prednison, vincristină, adriamicină şi imatinib (cromozom Philadelphia pozitiv). La 2 săptămâni de la terminarea tratamentului pacientul a prezentat tuse seacă, uscată şi sindrom febril. Pacientul a fost internat in Clinica de Hematologie cu sindrom febril, rinoree şi insuficienţă respiratorie. Examenul hematologic a relevat pancitopenie şi creşterea gradientului de oxigen alveolo-arterial. Radiografia toracică a evidenţiat infiltrate pulmonare bilaterale, difu-

ze. Se instituie tratament cu antibiotice cu spectru larg suspicionându-se o pneumopatie . Starea generală a pacientului se alterează progresiv cu apariția obnubilării şi a unei stări confuzionale. Examenul prin tomografie computerizată a permis identificarea unei leziuni frontale drepte cu edem perilezional şi aspecte similare în regiunea talamică stângă. Puncția lombară a evidențiat o presiune de 180 cmH_2O, leucocite $1/mm^3$, proteine 30 mg/dl, glucoză 40 mg/dl. Testul ELISA a fost pozitiv (fig. 1).

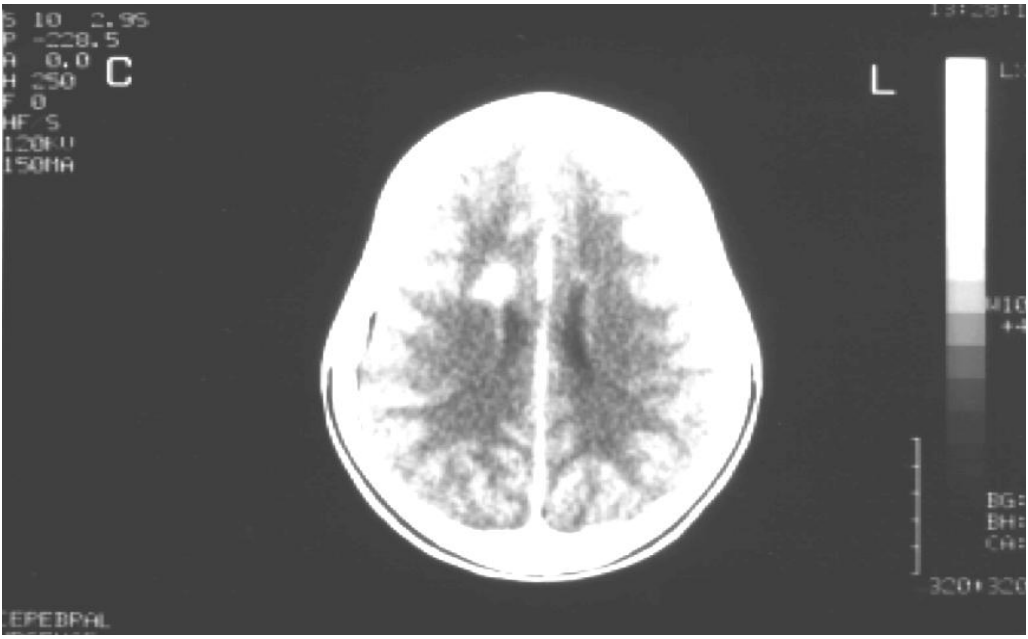

Fig. 1. Tomografia computerizată cerebrală

REZULTATE ŞI DISCUȚII

Examenul serologic pentru *T. gondii* a fost pozitiv pentru IgG şi negativ pentru IgM. Lavajul bronhioloalveolar (LBA) a identificat prezența de *T. gondii*.

Deşi manevrele terapeutice au fost intensive, insuficiența respiratorie a progresat rapid şi s-a impus suport ventilator. Pacientul a decedat în următoarele 72 de ore prin insuficiență de organ multiplă.

Ca şi in cazul nostru, toxoplasmoza pulmonară se traduce frecvent prin pneumopatie interstițială febrilă care asociază tuse seacă şi dispnee şi poate evolua spre insuficiență respiratorie acută. Datorită frecvenței scăzute a acestui sindrom clinic, diagnosticul de toxoplasmoză pulmonară poate fi uşor omis mai ales în contextul unor expresii clinice şi radiologice nespecifice (4, 5).

Vizualizarea directă a tahizoizilor pe preparatele Giemsa se caracterizează printr-o sensibilitate redusă şi depinde de medicul anatomopatolog care realizează interpretarea. În acest context se impun efectuarea unor tehnici de diagnostic moderne, rapide şi efective de tipul PCR, dar limitate de posibilitățile tehnice ale spitalelor din sistemul de stat.

Diagnosticul toxoplasmozei pulmonare

este astfel dificil şi se caracterizează prin absența unui aspect patognomonic clinico-radiologic deoarece rareori poate fi considerată cauză majoră a pneumoniei. În cazul pacienților imunosupresați infecția cu *T. gondii* poate fi mascată de alte semiologii infecțioase ceea ce face ca diagnosticul corect biologic şi serologic să fie delicat, cu o rată de supraviețuire de până la 15% (6).

Serologia constituie baza diagnosticului la pacienții imunocompetenți, dar interpretarea testelor serologice specifice devine dificilă în condițiile unui status imunodeprimat. Pacienții sunt frecvent IgG specifici, iar IgM apare doar în 6-12% din cazuri. Avantajul observării directe a prezenței parazitului în lichidul obținut prin lavaj bronhoalveolar(LBA) are o valoare predictiv pozitivă de 90% şi poate fi argumentată până la 100% prin biopsie pulmonară (7).

Introducerea metodelor moleculare (PCR) poate ameliora considerabil diagnosticul toxoplasmozei mai ales în formele pulmonare. Aşa cum arată studiile de specialitate, sensibilitatea PCR este de 100% în cazul toxoplasmozei indiferent de laboratorul în care se efectuează explorarea. În consecință, rata de supraviețuire poate creşte până la 60% la pacienții imunodeprimați infestați cu toxoplasma (8).

În cazul prezentat, toxoplasmoza a fost diagnosticată prin examinarea LBA, plămânul fiind al 2-lea organ afectat în cazul toxoplasmozei extracerebrale. Infecțiile cu oportuniști la pacienții imunosupresați nu sunt rare şi explică deterioarea stării clinice cu sindrom de detresă respiratorie acută şi MOFS diagnosticate în cazul inclus in studiu.

T. gondii modulează expresia genică a celulelor endoteliale cerebrale favorizând migrarea prin bariera hemato-encefalică. Mortalitatea este mai mare la pacienții imunodeprimați. Seroprevalența creşte direct proporțional cu înaintarea în vârsta, iar afectarea toxoplasmotică devine multiorganică. Dacă la pacienții imunocompetenți infecția este, în general, asimptomatică, la cei imunodeprimați tabloul clinic este sever şi reprezintă de obicei reactivarea unei afecțiuni subclinice prezentate anterior. Simptomele localizării cerebrale asociază febră, cefalee şi stare confuzională care pot progresa până la comă şi deficite neurologice focale. Limfadenopatia nu este frecvent întâlnită, iar parazitul poate fi responsabil de inflamarea neurogenică ce apare în diferitele tipuri de cefalee. Simptomele evoluează în zile şi săptămâni iar toxoplasma se localizează, predominant, în ganglionii bazali determinând hemicoree, hemibalism, parkinsonism sau tremor. Encefalita difuză apare în stadiile incipiente chiar în condițiile unui examen imagistic normal. Analiza LCR relevă pleiocitoză mononucleară cu creşterea proteinorahiei şi niveluri normale sau scăzute ale glicorahiei (4, 6).

CONCLUZII

Afectarea pulmonară în toxoplasmoza la pacienții imunodeprimați este frecvent, sublinică şi asociază determinări cerebrale. Investigarea LBA este o metodă eficientă de diagnostic. Mortalitatea este crescută, cauza principală fiind apariția insuficientei multiple de organ (MOFS)determinată de afectarea multiorganică.

Si in cazul nostru tusea, sindromul febril şi insuficiența respiratorie s-au dovedit a fi simptomele de alarmă, situație comună pentru pacienții imunodeprimați infestați cu *T. gondii*.

NOUTĂȚI

QUORUM QUENCHING: O NOUĂ STRATEGIE DE LUPTĂ ANTI-INFECȚIOASĂ PRIN INTERFERENȚA SISTEMELOR DE COMUNICARE INTER-BACTERIANĂ

Numeroase funcţii bacteriene, precum virulenţa şi producerea de biofilme, sunt controlate de un mecanism de comunicare depedent de densitatea celulară cunoscut sub numele de Quorum Sensing (QS). Acest mecanism se bazează pe eliberarea unor molecule mici, difuzibile, care permit bacteriilor să-şi coordoneze comportamentul în funcţie de densitate. Interferenţa cu aceste sisteme de semnalizare, numită Quorum Quenching (QQ), reprezintă o perspectivă atrăgătoare pentru combaterea infecţiilor bacteriene. Controlarea producerii biofilmului de către sistemele QS extinde, în perspectivă, aplicabilitatea QQ, făcând posibilă rezolvarea problemelor legate de formarea biofilmelor implicate în boala periodontală. În plus, dat fiind faptul că biofilmul creşte rezistenţa bacteriilor la acţiunea substanţelor antimicrobiene, QQ ar putea reprezenta o nouă metodă de luptă contra tulpinilor nosocomiale multirezistente. (Romero M, Acuna L, Otero A. Patents on quorum quenching: interfering with bacterial communication as a strategy to fight infections. *Pat Biotechnol* 2012; 6(1): 2-12).

NEW DATA OF BLOOD TRANSFUSION IMPORTANCE IN PATHOLOGY (Abstract): Blood transfusion is a very important aspect of clinical hematology. An essential particularity is the correctly use of blood products because it can cause immediate or delayed complications. Transfusion security and efficiency requires integrated strategies and the purpose of the transfusion is to provide the patient with blood components to improve their hematologic status. From a single total blood donation can be obtained multiple type of blood components. Transfusion centers are capable of separating plasma erythrocytes, or of other products such as platelet concentrates, or cryoprecipitate named 'labile blood products'. On the other side plasma derivates, are made by fractionation of plasma. All the blood components to bring benefit must be viable when transfused. The blood or the resulting compounds must be preserved, transported and stored under conditions that meet quality criteria and follow the standardized procedures. **Keywords**: BLOOD PRODUCTS, BLOOD TRANSFUSION

Transfusion of blood components and the differential diagnosis or treatment of acute transfusion reactions represent conditions of great importance for clinicians, nurses, clinical laboratory and the transfusion centers. This is a reason to discuss some base directions concerning some of the blood transfusion preanalytical tests, use of blood products for transfusion in pathology and management of transfusion reactions. In a healthy person who does not have a bleed, a hemoglobin concentration of 70-80 g/L is normally sufficient to maintain oxygenation of the tissues. This is the partial effect of an improved microcirculation caused by a low blood viscosity. Therefore, in this context, erythrocyte transfusion is normally not necessary unless hemoglobin falls below this level. However, if the compensation mechanisms are not sufficient to adequately increase the cardiac output, for example due to heart failure and/or pulmonary function or sepsis, a higher level (90-100 g/L) may be appropriate.

General principles in blood transfusion

There must be documented procedure, standards and a good laboratory practice in

quality management system for the safety of the patient. There are some basic blood transfusion rules such as (1):

1 - assessment of the need for transfusion

2 - assessment of the benefits and risks of transfusion

3 - patient will receive that blood component he needs

4 - administration of blood or blood derivatives will be made taking at least the blood group into the OAB, Rh, Kell systems of the donor and the recipient

5 - correct and complete performance of the pre-transfusion compatibility test

6 - precise patient identification

7 - last check at the patient's bed

8 - using alternatives to blood transfusion whenever is possible and reducing the number of transfusions that are not necessary.

The pre-transfusion protocol

Pre-transfusion testing include laboratory testing necessary for compatibility between the blood of the transfusion recipient and the blood product intended for transfusion.

This process includes the following (2):

a) determination of ABO and Rh (D) blood group in the patient; in the case of infants and infants up to 6 months, the Coombs direct test will also be performed to confirm the ABO blood group; b) in special situations (newborns, infants, children, multiple transfusion, fertile age women, transplants, immunosuppressed, immunized), it is necessary to carry out blood group determinations in other erythrocyte antigenic systems;

c) detection of irregular anti-erythrocyte antibodies in immunized and multiple transfusion patients;

d) verifying the macroscopic aspect, integrity, ABO and Rh (D) blood group in the blood unit or blood component selected for compatibility testing

e) compatibility test between patient and total blood unit or blood component. All three complementary techniques - saline test, papain enzyme assay at 37°C, indirect Coombs test will be performed.

The last pre-transfusion control means:

a) checking the identity of the patient;

b) checking the macroscopic appearance and integrity of the transfusion unit;

c) checking the compatibility between the selected blood unit and the patient:

- determination of ABO and Rh (D) blood group in the patient;

- ABO and Rh (D) blood group determination at the transfusion unit;

- documentary verification;

- recording in the score sheet.

Traceability of blood components

Refers to the principle that all blood/blood components must be traceable from the donor to the patient and in reverse from the patient to the donor. It is an integral part of providing a safe blood service to patients. Traceability, which is a preliminary condition for hemovigilance, can be defined as the ability to follow each unit of blood or blood components from the time of collection from the donor to the destination, whether it is a patient, a manufacturer of medicinal products or a disposal center, and vice versa. This include the amount of recorded information and of measures that allow the tracking and identification of each stage of the activity, from the person's admission to donation to the therapeutic use of blood and human blood components; traceability allows establishing a link between the donor and one or more recipients

and from the recipient to the donor, being established using a unique national system for identifying blood units and individuals (3).

Traceability is essential for identify:

• retrospectively a potentially infected donor in case of transmission of an agent to a beneficiary;

• retrospectively a potentially infected recipient in the case of an infected donor;

• beneficiaries in case of systemic problems that expose beneficiaries to the risk or episodes of serious side effects.

Also, traceability can provide information about the total number of transfused patients, blood units or components issued or used and blood donors who have provided transfused blood units or components.

Blood products used in specific clinical situations

Acute blood loss

Initial measures taken to manage acute blood loss are aimed to stop bleeding by treating any traumatic, surgical or obstetric source and keeping the blood flow within the organs in critical condition. If organ and tissue oxygenation is severe affected, red blood cell transfusion may be needed to improve tissue oxygenation. The need for a erythrocyte transfusion should be evaluated individually and based on clinical signs and critical evaluation of laboratory test results. Hemoglobin and hematocrit values should be measured frequently but considering that they may be a poor indicator of blood loss in the acute situation.

Massive transfusion can be defined as replacing the patient's total blood volume with donated blood in less than 24 hours, replacing 50% of the blood volume within 3 hours, or transfusion to compensate blood loss that exceeds 150 mL per minute (4). Early recognition of lost blood amount and effective action are needed to prevent the shock and its consequences. Effective communication between clinicians, diagnostic laboratories and blood banks is of major importance and a massive transfusion procedure/protocol (MTP) is recommended.

Correction of coagulopathy in this context requires the judicious use of blood component therapy (erythrocytes, platelets, fresh frozen plasma, and, in some cases, cryoprecipitate or fibrinogen concentrate and pharmacological agents).

Chronic anemia

The treatment of chronic anemia due to deficiency of iron, folic acid/vitamin B_{12} should be primarily directed to correct the cause of anemia. Transfusion of erythrocytes is rarely necessary. When measures to correct the cause of anemia are ineffective, erythrocyte transfusion may be considered (5). The decision to perform a transfusion should be based on the clinical condition of the patient, considering the level of hemoglobin, the duration of anemia and the presence of conditions affecting the transport of oxygen, such as pulmonary insufficiency, cardiac disease or cardiovascular disease. In chronic diseases such as uremia and malignancies, increasing anemia is significantly associated with increased fatigue, which has a significant negative impact on functional abilities and patient quality of life. Transfusion therapy in chronic anemia, such as that associated with malignancy, usually has the goal of maintaining hemoglobin levels between 80 and 100g/l, while a level of >100g/L may be adequate for some patients, to avoid angina or heart failure.

The need for transfusion should be as-

sessed individually and should consider the fact that different patients need different transfusion support to maintain an acceptable social situation and maintain their physical performance but also to experience a satisfactory quality for the life. Regular transfusion therapy, although effective, has several disadvantages. The effect is short-lived and there is a risk of overloading with iron, which can harm the body. Treatment with erythropoiesis stimulating agents (ESA) to maintain hemoglobin up to 120 g/L is usually effective in the treatment of anemia in patients with renal impairment but not all patients respond to this treatment. ESAs should be used with caution in cases of malignant tumors and its use is contraindicated in some cancers, while in other cases it may be ineffective. Larger use of ESA in the treatment of chronic anemia will depend on their cost, effectiveness and safety. In patients with thalassemia and those with severe, chronic, life-threatening hemolytic anemia, transfusion therapy involves regular lifetime blood transfusions, usually given every 2-5 weeks, to maintain hemoglobin pre-transfusion greater than 90-105 g/L.

It has been shown that this moderate transfusion regimen promotes normal growth, allows normal physical activity, appropriately suppresses bone marrow hyperactivity in most patients, and minimizes iron accumulation. Higher hemoglobin pre-transfusion levels (110-120 g/L) may be more appropriate in patients with heart disease or other medical conditions, and in those patients where adequate bone marrow suppression is not achieved at lower hemoglobin levels.

In siclemia, the indications for transfusion therapy with erythrocytes are anemia and vascular occlusion. Transfusion therapy is not normally indicated in patients with hemoglobin values greater than 70 g/L. In the presence of vascular occlusion, the goal of transfusion therapy is to prevent or stop intravascular formation of sickle-shaped cells by diluting or replacing circulating pathological erythrocytes with the normal one. Patients with sickle cell disease should be transfused with erythrocytes that has no hemoglobin S. Patients with these conditions are unlikely to develop vaso-occlusive episodes when the percentage of hemoglobin S is less than 30%. Exchange of erythrocytes may be necessary in major elective surgery, ocular surgeries, and to prevent or treat acute vaso-occlusive episodes.

Acute autoimmune hemolytic anemia (AAHA)

Transfusion should normally be avoided in this context but may be necessary in life-threatening situations despite serological incompatibility (6). This anemia is caused by the acute destruction of the red blood cells by autoantibodies directed against its own antigens from the erythrocyte membranes or against modified structures of the patient's red cell membrane. The target antigens of these autoantibodies are often antigens present in most blood donors, and transfusion is therefore less effective. In an autoimmune hemolytic anemia, it is very important to correctly diagnose the type of AAHA

1. **Warm antibody autoimmune hemolytic anemia** type Ig G (with IgG type circulant autoantibodies that bind to erythrocyte antigens at a temperature of 37°C. It is mainly found in lymphoproliferative syndromes (type B, LLC) lupus erythematosus disseminated and occasionally with different cancers/may be idiopathic. Rare-

ly, autoantibodies may be IgM / IgA type and hemolysis are predominantly extravascular.

2. **AAHA with cold-IgM antibodies** (Cold agglutinin disease)-manifested as a chronic disease, often associated with macroglobulinemia, LLC, or in transient forms during the complications of infectious diseases encountered in children.

The autoantibodies are IgM type and intravascular hemolysis is possible

3. **AAHAI mixed type** were the autoantibodies are IgG and IgM.

Thrombocytopenia

The purpose of platelet transfusion is to prevent and treat hemorrhage in patients with thrombocytopenia or platelets dysfunction. The decision to transfuse the platelet components should be based on the platelet count, the clinical condition of the patient and the clinical context. Normally, before deciding on the use of platelet transfusion, the cause of thrombocytopenia should be determined (7). Platelet transfusions are not indicated in all causes of thrombocytopenia and may be contraindicated in certain conditions.

In thrombocytopenia due to primary or secondary bone marrow failure, thrombocyte therapeutic transfusions are indicated for patients with active hemorrhage associated with thrombocytopenia. Thrombocyte therapeutic transfusions are used when the platelet count is less than $5\text{-}10x10^9$/L and in the absence of hemorrhage or another platelets-consuming factor. The presence of fever, local lesions, coagulation disorders and/or other unwanted symptoms may require prophylactic transfusions to maintain a platelet count of $>15\text{-}20x10^9$/L.

In chronic failure of platelet production caused by aplastic anemia or myelodysplasia, long-term prophylactic transfusions should be avoided due to the risk of HLA/HPA alloimmunization and platelet refractoriness. Many patients do not suffer from severe hemorrhage, despite the $5\text{-}10x10^9$/L platelets. If platelet transfusions are needed, the interval between transfusions should be evaluated individually.

In thrombocytopenia and surgical procedures or invasive procedures platelet transfusions should be considered to maintain a platelet count greater than $50x10^9$/L in patients to be undergoing a major invasive procedure or in situations where direct hemostasis is not possible (liver or transbronchial biopsies). Higher platelet levels ($>100x10^9$/L) may be required in clinical contexts involving major bleeding risks (intraocular or neurosurgical procedures) (8).

In case of patients with platelet function disorders rarely require platelet transfusions. The cause of impairment of the function (drugs affecting the platelet function) should be identified and corrected, if possible, prior to surgery or invasive procedures. Platelet transfusion should be considered in patients with platelet function disorders when the patient requires an invasive procedure and there is an increased risk of bleeding. In this context, the platelet count is not a reliable indicator of the risk of bleeding and the platelet transfusion should be continued until the risk of bleeding has ceased. Transfusion could also be indicated in spontaneous hemorrhages that do not respond to simple local treatment or other measures.

Clinical indications
for fresh frozen plasma (FFP)

The purpose of FFP transfusion is to correct clotting irregularities in a patient

with hemorrhage with a deficiency of multiple coagulation factors. FFP has very few indications. It can be used in situations where there are several deficiencies in coagulation factor or in case the deficiency of a single coagulation factor if a concentrate for the coagulation factor with reduced pathogens is not available. The clinical effects of FFP transfusion are often difficult to evaluate. The clinical response may indicate the efficacy of fresh frozen plasma transfusion, especially in hemorrhagic patients (9). When FFP is transfused to correct abnormal levels of hemostatic variables, the effect should be monitored both to support decision-making on continued treatment. Monitoring clinical signs and hemostatic variables will help assess the suitability of the assistance and help in selecting components but should not delay the initial release of FFP.

Surgical bleeding and massive transfusion

There is considerable debate about the proper mixing of blood components used in early management of patients with massive blood loss. Observational studies have suggested that an initial percentage of FFP: Erythrocytes of 1:1.5 is associated with decreasing mortality. These transfusion protocols should be supplemented with clinical signs and appropriate coagulation tests. FFP should be used to maintain prothrombin time and partial thromboplastin time at approximately 1.5 times normal or less and to maintain fibrinogen above 1.0 g/L.

Disseminated intravascular coagulation (DIC)

Activation of fibrinolytic and coagulation systems consumes proteins and coagulation inhibitors, fibrinogen and platelets. Clinical presentation may range from major hemorrhage (with or without thrombotic complications) to a compensated condition diagnosed only with laboratory tests (10). Acute DIC is most likely to occur when the coagulation (and fibrinolytic) system is massively activated by the underlying disease, and natural inhibitors do not balance this massive activation. The primary cause of DICC should be treated. FFP, plasma support, platelets and fibrinogen or cryoprecipitate concentrate may be necessary if the patient is hemorrhagic. An initial dose of 15 ml/kg of FFP is recommended, although there is evidence that a dose of 30 mL/kg causes a higher recovery of coagulation factor levels.

Deficiencies of a single coagulation factor

FFP can only be used when a coagulation factor concentrates required to treat single coagulation factor deficiency is not available. Currently, it is mainly applied only to the rare inherited deficiency of the coagulation factor V.

Hepatic diseases

The bleeding tendency is caused by the reduction in coagulation factor synthesis, dysfibrinogenemia, thrombocytopenia and increased fibrinolysis. If there is active bleeding, support treatment with FFP may be necessary. The response to the FFP cannot be predicted when it comes to correcting abnormal test results before invasive procedures in patients with liver disease. The routine use of FFP has been challenged in this case. If FFP is given, coagulation tests will be repeated, and future therapy will be determined based on the results of these tests.

Thrombotic Thrombocytopenic Purpura (TTP)

The accumulation of high molecular weight molecular weights of Willebrand factor (HMW-vWF) due to a deficiency of the metalloproteinase enzyme (ADAMT13) leads to the activation and consumption of platelets. Plasma exchange with FFP should be performed as soon as possible, preferably within 24 hours of symptom manifestation. Daily plasma exchange should continue for at least 2 days after remission

Clinical use of granulocytes

The purpose of granulocyte transfusion is to improve the clinical status of patients with severe and infected neutropenia who do not respond to appropriate antibiotic therapy. These are rarely necessary. Granulocyte transfusion should only be used in patients with neutropenia that meet all the following criteria:

- the number of neutrophils is less than 0.5 x 10^9/L due to congenital or acquired medullary insufficiency;
- more than 24-48 hours, proven or highly probable fungal or bacterial infection, lack of response to appropriate antifungal therapy or antibiotic therapy;
- the hope of recovering the number and function of neutrophils or if bone marrow transplantation is planned;
- patients with severe or congenital granulocytic dysfunction, regardless of granulocyte count, or with a fungal infection or bacteria that is proven or suspected to be life-threatening, and who do not respond to appropriate antibacterial or antifungal therapy for at least 48 hours. Prophylactic granulocyte transfusions are not recommended (11).

Transfusion in obstetrical practice

Major obstetric hemorrhage remains an important cause of maternal death. Inappropriate transfusions during pregnancy and the postpartum period expose the mother to the risk of hemolytic disease of the fetus and newborn (HDFN) in subsequent pregnancies. Prevention and treatment of anemia in pregnancy (usually iron deficiency) avoids unnecessary blood transfusion (12). A blood count should be checked at the antenatal booking visit and at 28 weeks (allowing sufficient time to treat iron deficiency before delivery). Oral iron replacement is appropriate for most patients, but intravenous iron (after the first trimester) may produce a more rapid response and should be used in women intolerant of oral iron. Transfusion is rarely required in hemodynamically stable pregnant women with Hb >70 or 80 g/L unless there is active (or a high risk of) bleeding. Cytomegalovirus (CMV) seronegative red cells should be provided for elective transfusions in pregnancy but standard, leuco depleted units may be used in an emergency to avoid delay (13). Successful management depends on well-rehearsed multidisciplinary protocols, rapid access to red cells (including emergency group O negative units) and excellent communication with the transfusion laboratory. Access to cell salvage reduces use of donor blood and early administration of tranexamic acid may reduce mortality. Pregnancies potentially affected by HDFN should be managed by specialist teams with facilities for early diagnosis, intrauterine transfusion and support of high dependency neonates. Clinical audits show that many transfusions in pregnancy, especially in the postpartum period, are inappropriate and could be prevented by better antenatal monitoring and

the targeted use of iron supplements (14). The decision to transfuse should be made after careful clinical assessment rather than based on a specific Hb concentration.

CONCLUSIONS

The decision to apply for blood transfusion therapy is taken by the clinician only in cases where all alternative methods have been used to solve the problems related to the treatment of the patient.

The doctor bears responsibility for the benefit or risks of blood transfusion and all risks should be considered, especially immunological and infectious. Nevertheless, the transfusion benefit must be greater than the risks.

Plasma management allows most blood transmissible infections to be transmitted and the use of blood and blood derivatives proper, means the use of blood products exclusively for the treatment of conditions that cause morbidity or mortality that cannot be prevented or treated by other means.

THE ROLE OF SPECIFIC IgE TO EVOLUTION AND PROGNOSIS OF COW'S MILK PROTEIN ALLERGIES IN CHILD (Abstract): Cow's milk allergy affects 8% of infants less than 1 year of age. The allergy is usually transient, with most children tolerating ingested cow'milk by age 3 years. This prospective study analyzes the clinical course, development of tolerance and risk for other atopy (asthma, rhinoconjunctivitis, atopic dermatitis) in children with cow's milk allergy. **Material and methods:** We followed 71 infants hospitalized between January 2006 – January 2010 in two clinic of Pediatrics from Iaşi and Galați with gastro-intestinal, respiratory and skin signs and symptoms of cow's milk allergy. In this study were identified atopic symptoms and diseases, family history of atopy, measured serum total IgE levels and was evaluated development of tolerance to cow's milk. IgE levels was measured at diagnosis, 12 months after diagnosis and recovery tolerance to cow's milk. Patients were followed to acquire tolerance to cow milk. **Results**: The median age of patients was 7.57 months ±2.73DS. IgE-mediated cow's milk allergy was detected in 40.85% (29 cases) of children at diagnosis. After 12 months of follow 7 (24.14%) of 29 cases initially IgE positive became negative. The first rechallenge was carried out 12 months after diagnosis at mean age 1.6 years (95%CI, 1.5-1.6 years) and the result was positive in 12 cases of IgE negative group. All children (100% of cases) with IgE-negative cow'milk allergy were tolerant by 3.0 years old ($P < 0.0001$) compared to 70.73% in children with positive IgE. In the end 17.24% of patiens with IgE-mediated cow milk allergy presented respiratory and skin atopic sings. Are there significant differences about the persistent cow'milk allergy between the group of children with positive IgE compared to negative IgE. ($p = 0.1918$, 95% CI). **Conclusions**: Most children recover their tolerance to cow milk during childhood and those with negative IgE even at young ages. Patients with positive IgE have an increased risk for allergic diseases, food and inhaled allergens sensitization and development of persistent cow's milk allergy. **Key words**: COW'S MILK ALLERGY, IgE, SENSITIZATION, TOLERANCE, ATOPY

Alergiile alimentare, definite ca reacții alimentare netoxice cu mediere imună (1), reprezintă un domeniu relativ nou de cercetare, studiile statistice ale ultimelor decenii indicând faptul că acest tip de patologie afectează 1-2% din populația adultă şi se ridică până la un procent de 8% în cazul copiilor (2). La ora actuală, cele mai stu-

diate reacții alergice alimentare sunt cele mediate de IgE, dar, fiind vorba de tulburări deosebit de complexe, este foarte probabil să fie implicate mai multe mecanisme.

Cercetarea reprezintă un studiu prospectiv în care s-a urmărit evoluția clinică a alergiei la proteina laptelui de vacă (APLV) şi redobândirea toleranței la laptele de vacă, precum şi factorii de risc ce determină dezvoltarea altor alergii la copiii cu APLV. S-au analizat factorii care favorizează instalarea toleranței la laptele de vacă, precum riscul apariției astmului bronşic, rino-conjunctivitei, dermatitei atopice şi sensibilizarea la lapte de vacă persistența la copiii de vârsta mică.
